Over the long duration of the Archaic period, there was a gradual shift from small, highly mobile hunters and gatherers practicing a forager pattern to larger groups with a diversity of settlement types involving residential bases, temporary camps, strategically located cache sites and specialized resource collecting localities. This pattern reflects increasing intensification and a shift from foragers to collectors who practiced logistical patterns of mobility to accommodate seasonally available resources. Coincident with these changes were the diversification of food resources and new specialized technologies with which to exploit them. Projectile points reflect the shift to the use of atlatl and dart. Milling tools become ubiquitous and reflect increased exploitation of seeds and nuts. Larger residential base sites tend to occur at reliable water sources such as springs or tanks, with temporary camps near seasonal stream channels, extinct rivers, playas, high terraces above sinks and rockshelters.

Some later Archaic sites are known, however, from the Colorado Desert that indicate occupations along the boundary between the low desert and Peninsular Ranges and at more favored habitats at springs and tanks. The most substantial Colorado Desert site is Indian Hill Rockshelter in Anza-Borrego Desert State Park where 1.5 m of Archaic period deposits were excavated below a Late Prehistoric component. Most significant were 11 rock-lined cache pits and numerous hearths indicative of either a residential base or a temporary camp in which food and tool storage was integral to the hunting and gathering settlement-subsistence strategy. Also recovered were numerous Elk-eared dart points, flaked and milling stone tools and three inhumations, one of which was radiocarbon dated to 4070 "100 B.P." Two similar rock-lined pits were excavated at a small rockshelter in Tahquitz Canyon near Palm Springs. The small quantity

of artifacts at that site suggested strategically stored food and seed processing equipment of small mobile groups.

Late Historic Period (1500–100 B.P.)

The major archaeologically visible technological and cultural innovations of this period are the introduction of pottery making by the paddle-and-anvil technique, bow-and-arrow technology around 1200 B.P., a shift from inhumation to cremation burial and the introduction of floodplain agriculture on the Colorado River about the same time, although exact dating of early domesticates is lacking. This was also the period when obsidian trade relations shifted from the Coso sources in the Mohave Desert to the Obsidian Butte source in the Salton Trough, when Lake Cahuilla did not submerge it. Ceramics and cultigens were introduced from either Mexico or through the Hohokam culture of the Gila River.

The ancestral Cahuilla were certainly exposed to domesticates at an early time, although opinions differ on when they adopted horticulture as a substantial part of their economy. It may have been a secondary pursuit for the production of specialty foods and fibers or gourds in the prehistoric period, although that has not been established archaeologically, as yet. Agricultural intensification and ditch irrigation techniques may not have occurred until after exposure to the mission system in historic times.

Bow-and-arrow technology, seed-beaters and other sophisticated hunting and gathering technology may also be related to the spread of Numic and Takic peoples from the southern Great Basin. Late Holocene flooding of Lake Cahuilla may have accelerated contacts between people of the ancestral Yumans of the Colorado River and the ancestors of the Cahuilla in the Coachella Valley and Peninsular Ranges. Such contacts through ceremonial and economic exchange may have resulted in a cultural dynamic that formed the Patayan Pattern and the resulting cultures of the ethnohistoric period. Long-range travel to special resource collecting zones and ceremonial locales, trading expeditions, and possibly some warfare are reflected by the numerous trail systems throughout the Colorado Desert. Pot drops, trailside shrines and other evidence of transitory activities are associated with these trails. Many of the pictographic, petroglyphs, and bedrock grinding surfaces in the Colorado Desert have also been associated with the Patayan pattern, although direct dating and cultural affiliation of such features is often difficult.

Ethnohistoric Period

Cahuilla and related Takic ("Shoshonean") speakers of the Uto-Aztecan linguistic stock such as the Luiseño, Serrano, and Gabrieleño, migrated from the southern Great Basin into California to displace the groups who had been occupying those territories. Those displaced groups are presumed to be the ancestors of the modern Hokan speakers who now occupy the areas to the

south (Kumeyaay) and the north (the Chumash). The specific time, duration, and process of this migration remains unclear. Some estimates based on glottochronology and distribution of archaeological assemblages put the transition somewhere between 1000 to 2000 B.P., mostly likely around 1500 B.P. but possibly as early as 2500 B.P.

The first documented description of Cahuilla Indians is provided by the chroniclers of the Anza Expeditions, whose mission was to bring colonists from Sonora to coastal California Their first trip brought them through Cahuilla territory in March 1774, the second in December 1775. Their first substantive encounter was at San Gregorio in the Borrego Valley, where they found Cahuilla ("Jecuiche") in apparent co-residence with Kumeyaay ("Cajuenches"). They continued to encounter Cahuilla through lower Collins Valley, Coyote Canyon, Cahuilla Valley, Tripp Flats, on the western side of the San Jacinto Mountains. Their observations were few but included references to the early spring agave harvests, seed gathering with beater and basket, rabbit sticks, agave fiber capes, and bows and arrows. Although possibly Serrano, a rockshelter composed of boulders and covered with brush is also described. The Spaniards describe the Cahuilla as weary of their presence, suggesting little or no previous contact, and apparently undergoing food stress, especially during the winter of 1775–1776 visit. This might be expected if stored foods in fall had been depleted and prior to the agave harvest.

The distance of Cahuilla territory from the California missions, first founded in 1769, meant they were not recruited in as great numbers, nor assimilated as rapidly as the coastal tribes. The first to enter Mission San Gabriel, possibly as early as 1783, were western Cahuilla of the kupakik lineage at Warner's Hot Springs. Next were Cahuilla wives of Serrano in the Cajon Pass area in the 1796. Members of western Cahuilla villages first appear in baptism records of 1797. In addition, runaway neophytes, especially Serrano, sought refuge among the desert tribes, exposing more isolated Cahuilla to mission ideology and material culture, not to mention diseases. It is not until after 1810, however, that Cahuilla individuals begin to appear in more substantial numbers in the registers of Mission San Gabriel, San Juan Capistrano, and San Luis Rey.

The impact of the Spanish mission system and colonization was generally much less immediate and profound to the isolated desert and mountain groups than coastal groups. More direct influence was not felt until after the establishment of the San Bernardino estancia in 1819 and, thereafter, a cattle ranch at San Gorgonio. When the Romero Expedition passed though the area in 1823–1824, it was clear that non-missionized Cahuilla were used to seeing vaqueros, employed by the rancho, driving cattle through the area. Certainly by 1823–1824, they were not only familiar with Hispanic ways but were comfortable in dealing with them, as evidenced by their reaction to the members of the Romero Expedition. The expedition also reported that the Cahuilla at Toro were engaged in agricultural pursuits (growing corn and melons) and were already familiar with the use of horses and cattle. While the Cahuilla may have already had some

experience in cultigens from their contact with the Colorado River tribes, agriculture probably became a more important supplement to their hunting and gathering economy after their exposure to ditch irrigation methods at the missions. Irrigation ditches were certainly being constructed by the Cahuilla in the Palm Springs area by the 1840s, and possibly several decades earlier.

Cahuilla political leadership with regard to external relations became more centralized in the Spanish and Mexican periods as high ranking or charismatic clan leaders were recognized by Europeans as representing entire tribal areas (Strong 1929:149). Emerging as central figures were Juan Antonio among the Mountain Cahuilla and Chief Cabazon in the desert. As early as 1844, Juan Antonio led several mountain clans to the San Gorgonio pass area to provide security for San Bernardino Rancho. His group played a significant role during the Mexican-American War, siding with the Mexicans against the Luiseño who supported the American invasion.

The 1848 Treaty of Hidalgo with Mexico obligated the Americans to preserve the liberty and property of the inhabitants of California, an obligation that obviously failed. The U.S. government in 1850 appointed three commissioners to conduct negotiations with tribal leaders across California to settle all land rights issues. One of the 18 treaties to be drafted covered the Cahuilla, Serrano, and Luiseño and was signed in Temecula on January 5, 1852. The tribal leaders were promised supplies, food, and technical training in return for accepting specified reservation lands. But as was so often repeated throughout the west, local Euro-Americans lobbied against the treaty and Congress never ratified it. The effect was to further alienate the traditional territorial base of the Cahuilla as whites flooded into the area to claim the best farming and grazing lands. Outside the reservations, Cahuilla men and women sought wage work on ranches in the San Jacinto and Santa Rosa mountains, and on farms, orchards, and urban households in the Riverside and San Bernardino valleys. This greatly accelerated the process of acculturation and Cahuilla participation in the regional socio-economic milieu.

European diseases were probably beginning to take their toll on the Cahuilla in the early 1800s but became particularly severe in the 1860s. The most dramatic was the great smallpox epidemic of 1863 that killed Juan Antonio as well as many bearers of tribal wisdom and culture. Survivors of previously autonomous clans assembled into the remaining villages or founded new settlements in an accelerated process of population aggregation and cultural reorganization. This process continued through the following decades. Isolated canyons now became places of refuge from disease and from contacts with Euro-Americans in general. Many previously occupied areas were abandoned in the 1860s and 1870s as residential bases but were still used for hunting and gathering into the twentieth century.

The Cahuilla land base was substantially reduced in the 1860s and 1870s as the federal government ceded every other section within ten miles of the new transcontinental railroad to the

railroad companies. Sections 16 and 36 of every township were also removed from federal control as a school tax base. Any de facto control of larger territorial bases was completely eliminated in 1876 when President Grant by Executive Order set aside small reservations for all groups classified as "Mission Indians." This included the sections or parcels in which they had aggregated in the previous decades and in which they had made improvements for farming, etc. The following year, another Executive Order by President Hayes set aside every even numbered section and certain other unsurveyed portions of townships for Indian reservations. The result was a checkerboard of Indian-controlled land, encompassing 48 sections, spread across the eastern edge of the Santa Rosa and San Jacinto mountains and the Coachella Valley. With various additions and withdrawals over time, this has remained the permanent home of the Cahuilla to the present.

As traditional lifeways became more difficult to pursue, the Cahuilla adapted to their new geographical and political environment by taking jobs in American ranches, towns, and cities. The 1860s through 1880s was a time of increased acculturation as new technologies, material goods, and practices were incorporated into the traditional lifeways of the reservation. Traditional ceremonial practices and beliefs continue along side Catholic and Protestant beliefs for many Cahuilla. Ceremonial houses still existed through the 1950s, 1960s, and early 1970s and many cultural traditions remain part of westernized lifestyles. The Cahuilla retain an acute interest in their cultural heritage and the cultural resources of their traditional territories.

Record Search Results

One historic resource was identified within the project area. The site is a bungalow style home located in the south-central portion of the project area adjacent to other existing buildings. The house was first recorded in 1982 by Laura Swift of the Riverside County Historical Commission.

In addition to onsite resources, five previously identified resources were identified within one mile of the site. Two of the resources are historic structures associated with farming in the area. One resource is the former location of historic structures and a Mission-era adobe rancho built around 1820. Another resource consists of the Colorado Aqueduct. The Aqueduct was built from 1933 to 1928 to transport water from the Colorado River to the Los Angeles Basin. One resource is the location of a historic event, the landing site of a record-setting trans-polar flight. This occurred on July 14, 1937, when a crew of three Russians landed their ANT-25 plane in agricultural fields after low fuel and fog forced them to abandon an attempted landing at San Diego. The 6,295-mile flight set a distance record and was only the second to cross the North Pole. The flight began in Moscow and lasted 62 hours, 2 minutes.

Site Survey Results

The site survey resulted the discovery of two isolated prehistoric artifacts. One previously recorded historic structure also exists within the project area. These resources include:

Historic Structure

The historic structure is a single-family home first recorded in 1981 by Laura Swift of the Riverside County Historical Commission. Swift estimated that it was built around 1926. However, a structure appears at the location on 1901 30-minute quadrangle maps. It is possible that the current home replaced an earlier structure. Evidence of such a replacement was not noted during the field survey.

The house is a front-gabled craftsman-style bungalow with a partial width front porch. The porch is also front gabled and both porch and house gable have triangular slatted vents under the gables. The front porch is enclosed by a low wall and rounded pilasters support the porch roof. The roof has widely overhanging eaves with exposed beams and triangular knee braces. The windows are all wood-framed double hung sashes with wooding casing.

The house has been abandoned since first recorded and is no longer maintained. It lies directly on an active fault (Casa Loma Fault) and the northeast corner has subsided 2-4 inches producing cracks on interior walls. All kitchen and bathroom cabinets, facilities and appliances were replaced, probably in the 1970s. Minor remodeling to interior spaces and partitions has also occurred. The north half of the attic was converted into a small bedroom loft with modern faux wood paneling. A small storage cellar is also located under the north half of the structure and is accessible by a stairwell in the kitchen. The unusual arrangement of windows on the north face of the house suggests other alterations may have occurred. Based on photos of the house taken during the original site survey (November 2004), the structure has further deteriorated with most of the windows being broken out and being marked with extensive graffiti.

One outbuilding which probably served as a tractor shed or garage was noted in the original field survey, but is no longer present at the site.

ISO-1 (Isolated Bifacial Mano)

An isolated bifacial mano (hand-held milling stone) was found near the crest of a subtle escarpment formed by an active fault that crosses the San Jacinto Valley. The floodplain of the San Jacinto River lies north of the escarpment. Otherwise, the area would have been a featureless alluvial plain in prehistory. The mano measures 10×8.2×5.7 cm and is made of coarse-grained granite. Both ends have been battered either to shape the mano into a desirable form or by being used as a pestle.

ISO-2 (Isolated Bifacial Mano)

An isolated bifacial mano (hand-held milling stone) was discovered 36 m south of ISO-1. The mano measures 8.5 cm in diameter and is 5 cm thick. It is made of hard, semi-crystaline quartz. About 70% of the circumference has been battered, probably to shape the object.

Despite good ground visibility and extensive searching, no additional artifacts were found in the vicinity of the two manos.

5.5.3 Significance Thresholds

Based on the criteria identified in Appendix G of the CEQA Guidelines, the proposed project would have a significant impact on cultural resources if it would:

1. Cause a substantial adverse change in the significance of a historical resource as defined in Section 15064.5?
2. Cause a substantial adverse change in the significance of an archaeological resource pursuant to Section 10564.5?
3. Disturb any human remains, including those interred outside of formal cemeteries?

NOTE: Due to the length of CEQA Section 15064.5, it is not repeated verbatim. Please refer to www.ceres.ca.gov for a description of CEQA Section 15064.5.

5.5.4 Impacts

The following discussion outlines potential impacts for the proposed project.

Would the project cause a substantial adverse change in the significance of a historical resource as defined in Section 15064.5?

While the historic structure has many features of a Craftsman-style bungalow, it has been substantially altered. All cabinets and plumbing fixtures have been destroyed. Interior walls have been altered by graffiti and many parts of the walls and ceiling have been punctured with holes that are beyond repair. The original wooden siding has been replaced by unusual textured pink stucco. In addition, a corner picture window has been inserted at the rear of the house.

The importance of a historic structure is related to survival of characteristics that existed during the period of significance. Historical resources must retain enough of their character or appearance to be recognizable as historical resources and to convey the reasons for their significance. Integrity is evaluated with regard to the retention of location, design, setting, materials, workmanship, feeling and association. The bungalow has been altered to the extent

that it has lost integrity of design, materials, workmanship and feeling. In fact, it is now barely identifiable as a Craftsman-style bungalow. It is unlikely that the bungalow retains sufficient integrity to be eligible for listing on the California Register of Historical Resources. Therefore, a less than significant impact to this formerly historic resource would occur.

Would the project cause a substantial adverse change in the significance of an archaeological resource pursuant to Section 10564.5?

No significant archaeological resources were identified within the project by either a records search or survey. One previously recorded historic structure and two newly identified isolated prehistoric artifacts were identified by the survey. Five previously recorded sites are located within one mile of the project. Due to the presence of these resources and the fact that the project is located within an alluvial setting, potentially significant archaeological resources could be unearthed during site grading. In order to reduce this potentially significant impact from occurring, mitigation is provided (see *Section 5.5.5, Mitigation Measures, Mitigation Measure 5.5-a*).

Would the project disturb any human remains, including those interred outside of formal cemeteries?

There are no known human remains within the site or vicinity. Additionally, the Native American Heritage Commission (NAHC) conducted a search of their Sacred Lands File, but found that Native American cultural resources were not present within one-half mile of the project area (See Appendix B). However, in the unlikely event human remains are found during construction activities, State Health and Safety Code Section 7050.5 states that no further disturbance shall occur in the immediate area until the County Coroner has made the necessary findings as to origin and disposition pursuant to Public Resources Code Section 5097.98. If the coroner recognizes the human remains to be those of a Native American, or has reason to believe that they are those of a Native American, he or she shall contact, by telephone within 24 hours, the NAHC who will then contact the appropriate tribal representative. Should local Native American groups find that the site supports potential buried ancestral remains, the Soboba Consulting Services Agreement allows for Native American monitoring during construction. Consequently, the project's adherence with the State Health and Safety, Public Resources Codes and Soboba Consulting Services Agreement shall ensure any potential impacts would be less than significant.

5.5.5 Mitigation Measures

5.5-a In order to reduce the potential for disturbance or damage to unknown archaeological resources, monitoring of mass grading activities of the site by a qualified archaeologist is required. Should the monitor observe disturbance of resources that could be important

archaeological artifacts, the monitor shall have the power to stop grading in the immediate area of discovery in order to allow for a resource study and recovery/curation effort (if necessary) to occur.

5.5.6 Residual Impacts/Level of Significance after Mitigation

Due to the lack of significant historic resources present, significant impacts would not occur. In order to reduce potentially significant impacts to unknown archaeological resources, mitigation is provided and would reduce any potentially significant impacts to a level below significance.

5.6 GEOLOGY AND SOILS

5.6.1 Introduction/Methodology

This section consists of a summary of existing geological conditions, anticipated impacts related to these conditions and mitigation measures required to reduce these impacts to a level below significance. A residual impact statement has been included to characterize the level of significance after applied mitigation measures.

A fault investigation for the project was performed by Leighton and Associates and their preliminary findings are presented in their report dated March 31, 2004. In order to evaluate the potential for surface fault rupture in the existing onsite Earthquake Fault Hazard Zone, ten exploratory fault trenches were excavated over a period of seven months. Findings were coordinated and reviewed with the County of Riverside Geologist and previous investigations completed on adjacent sites were also reviewed. In response to questions and comments received from the County Geologist, Leighton also prepared three additional investigations (reports dated August 31, 2005, June 30, 2006, and October 31, 2006). These investigations are included in *Appendix E* of this EIR and summarized in this section. Leighton and Associates conducted a preliminary geotechnical investigation which is summarized in the February 28, 2005, Preliminary Geotechnical Investigation. This second report is included as *Appendix F* to this EIR.

5.6.2 Existing Conditions

Subsurface Soil and Rock Conditions

The earth materials encountered throughout the site consist of undocumented fill, topsoil and alluvium. These units are described in the following sections in order of increasing age.

Undocumented Fill

Undocumented fills are related to grading activities to construct onsite access roads, perimeter unimproved dirt roads, site agricultural leveling and exploratory excavations (fault trenches). Other undocumented fills exist associated with limited water retention berms to collect seasonal runoff and the livestock run-off retention basin. All undocumented fills are considered unsuitable for support of additional fill or structures or other planned improvements in their present condition.

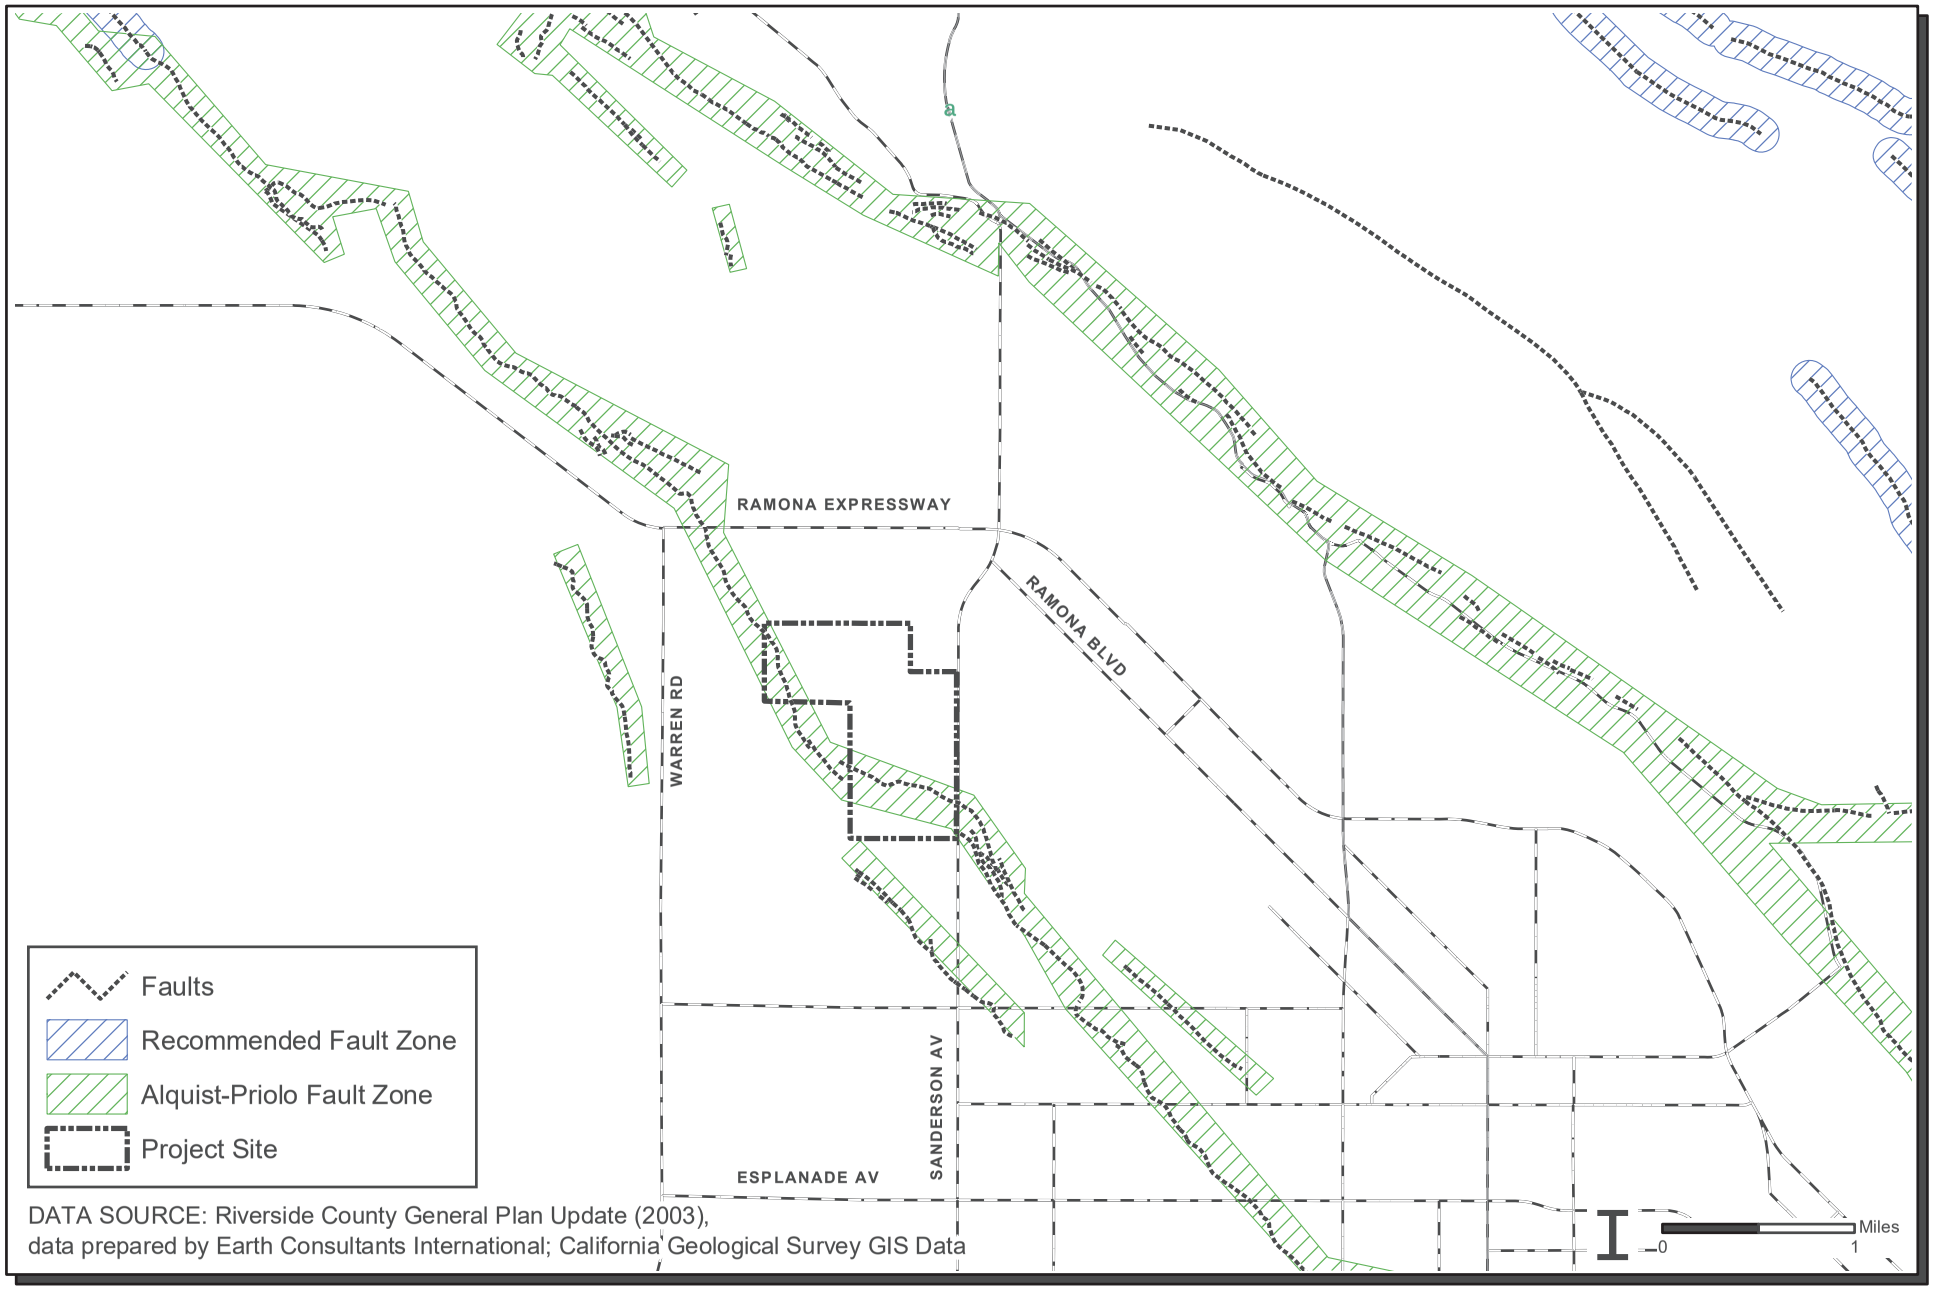
Topsoil

The majority of the site is composed of topsoil that is located on the upper 10 to 24 inches of the ground surface. Uniform in composition and thickness, this material general consists of a light

yellow-brown to yellow brown, silty sand, silty clay to sandy clay with scattered gravel sized clasts.

Alluvium (Qal)

Alluvial soil was encountered in all areas of the site and was deposited as part of a complex fluvial/channel dispositional environment. This alluvium consists of yellow-brown to medium gray, dry to damp, silty, very fine to fine sand, with interbedded lenses of silt. Channel deposits of homogeneous, friable, dry, medium to coarse sand with interbedded lenses and lamination of gray, loose to medium dense, dry to damp, very fine to fine sand were also observed. There are abundant in-filled animal burrows containing finer silt and sands.



Subsurface Water Conditions

Perched groundwater was encountered at multiple depths below the surface, as shallow as 5 feet and as deep as 22 feet. Regional groundwater is anticipated below 150 feet and likely, as much as 200 feet below grade. However, groundwater can be expected to fluctuate seasonally within the subject site and during periods of heavy regional rainfall, or groundwater withdrawal by the local residences, agricultural developments and water utility companies. During drought conditions, groundwater levels could temporarily deepen significantly.

Faulting and Seismicity

Based on the commonly accepted definition provided by the California Geological Survey, an "active fault" is a fault that has had surface displacement within Holocene time (about the last 11,000 years) and a "potentially active fault" is a fault considered to have had surface displacement during Quaternary time (last 1,600,000 years). These definitions are used in delineating Earthquake Fault Zones as mandated by the Alquist-Priolo Geologic Hazards Zones Act (California Public Resources Code Sections 2621–2630). The intent of this act is to prohibit the location of structures on the traces of active faults, thereby mitigating potential damage due to fault surface rupture.

The project site is located within seismically active southern California. The subject site contains an Earthquake Fault Zone (as created by the Alquist-Priolo Earthquake Fault Zone Act). According to the Leighton & Associates Fault Investigation, the active San Jacinto-Casa Loma fault transverses the northwestern and southern portions of the project site. Fault lineaments are shown by geomorphic evidence, aerial photography, and in the San Jacinto 7.5 minute Quadrangle of the Alquist-Priolo Earthquake Fault Map (see *Figure 5.6-1, Faults and Fault Zones*).

Villages of San Jacinto EIR

a t a t one

FIGURE

. -

INTENTIONALLY LEFT BLANK

In addition to the on-site Casa Loma, several other active faults are located in the project area. The San Jacinto Valley Segment of the San Jacinto Fault is located approximately 0.8 mile northwest of the site, the San Jacinto-Anza Fault is located 7.2 miles to the southeast, and San Andres Fault lies 15.7 miles to the northeast. *Figure 5.6-1* summarizes regional faults within the area. The San Jacinto Fault Zone is estimated to accommodate a plate slip of approximately 12–20 millimeters per year. Since the mid-18th century, at least six major earthquakes have occurred along the San Jacinto Fault Zone, ranging from 6.2Mw to 7.2Mw. Of all the fault systems in California, the San Jacinto and San Andreas Fault complexes are among the most active. The U.S.G.S. measures hundreds of minor earthquakes annually within the San Jacinto Valley. Most of these earthquakes are in the bedrock underlying the alluvium unit at depths of 3 to 5 miles.

Subsidence/Ground Rupture

Ground rupture is generally considered most likely to occur along pre-existing active faults. As such, the potential for site ground rupture during a seismic event is considered moderate to high. Based on historic occurrence data, ground rupture is believed to occur at normal recurrence intervals which may not provide adequate time for erosion to conceal fault features. Subsidence/rupturing of a portion of the San Jacinto graben has occurred at an apparent average rate of between 0.125 and 0.5 inch per year for at least the past 15,000 to 40,000 years (see *Figure 5.6-2, Subsidence Hazard Areas*).

Liquefaction

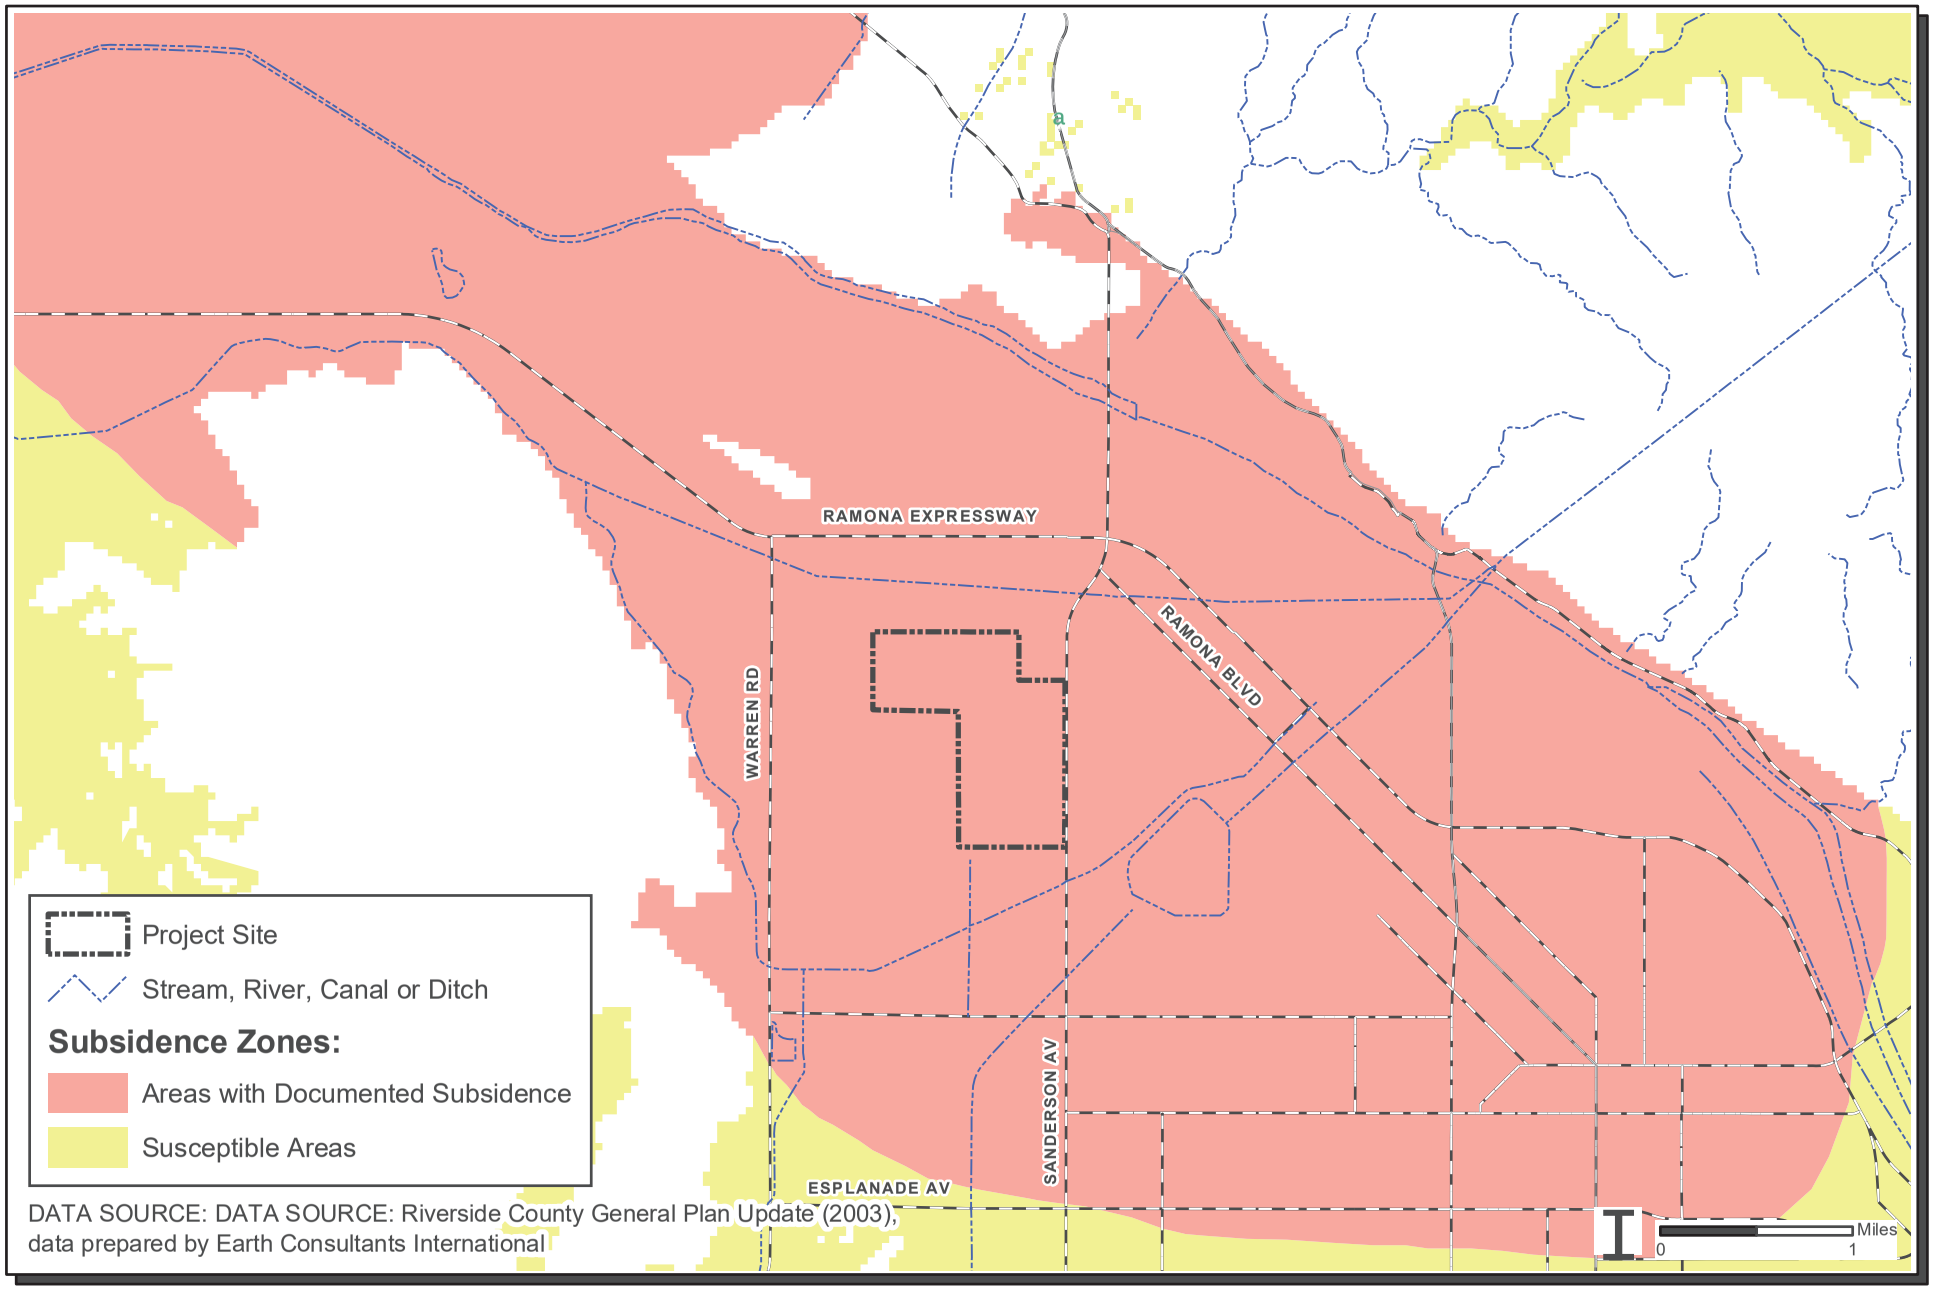
Liquefaction occurs when strong seismic activity creates excess pore pressures in cohensionless soils. Research and historical data indicate that loose granular soils or soils of low plasticity below a near surface groundwater table are most susceptible to liquefaction. Liquefaction is characterized by a loss of shear strength in the affected soil layers, thereby causing the soil to flow as a viscous liquid. This effect may be manifested at the ground surface by settlement and/or sand boils. In order for the potential effects of liquefaction to be manifested at the ground surface, the soils generally have to be granular or of low plasticity, loose to medium dense, saturated relatively near the ground surface and must be subjected to a sufficient magnitude and duration of ground shaking. Increased soil mobility can lead to lateral spreading, consolidation and settlement of loose sediments, ground oscillation, flow failure, loss of bearing strength, ground fissuring and other damaging formations. As depicted on *Figure 5.6-3, Liquefaction Hazard Areas*, the proposed project is located in an area with moderate potential for liquefaction. Upon further analysis, the Leighton Associates Report identifies the northern one-third to one half of the project site as having a potentially high possibility for liquefaction to occur given current site conditions.

Landslide, Mudflow or Other Erosion Hazards

Landslides are anticipated when severe weather events weaken certain agglomerations of hillside soils. As a result, unstable soil slips downhill. The proposed site is relatively flat with site elevations varying from approximately 1,457 feet above mean sea level along the northwestern boundary to an elevation of approximately 1,493 feet near the southeast corner. No previous landslides were identified during the investigation (see *Figure 5.6-4, Landslide Hazard Areas*).

Similar to landslides, mudflows occur during severe weather events in or adjacent to mountainous terrain. Large boulders and sediment are mobilized as a result of a sudden onslaught of water. This hazard is prone to occur in areas affected by fire that are relatively void of vegetation. The project is located in the San Jacinto River Valley, away from mountainous terrain. This hazard is expected to be minimal at this project site.

Any exposed soil surface may be susceptible to wind or water erosion. There are no naturally occurring drainages on site, therefore the likelihood of water-based erosion is unlikely.



Seiches and Tsunamis

A tsunami is a sea wave generated by submarine earthquakes, landslides or volcanic activity, which displaces a relatively large volume of water in a very short period of time. Seiches are defined as oscillations in a semi-confined body of water due to seismic shaking. The proposed project site is not located near a significant body of water or the Pacific Ocean. Therefore, these hazards are not anticipated at the project site.

5.6.3 Significance Thresholds

Based on the criteria identified in Appendix G of the CEQA Guidelines, the proposed project would have a significant impact on geology and soils if it:

1. Expose people or structures to potential substantial adverse effects, including the risk of loss, injury, or death involving:
    a. Rupture of a known earthquake fault, as delineated in the most recent Alquist-Priolo Earthquake Fault Zoning Map issued by the State Geologist for the area or based on other substantial evidence of a known fault
    b. Strong seismic ground shaking
    c. Seismic-related ground failure, including liquefaction
    d. Landslides.

FIGURE . -3

INTENTIONALLY LEFT BLANK

Villages of San Jacinto EIR

Lan i e a a ea

FIGURE . -

INTENTIONALLY LEFT BLANK

2. Result in substantial soil erosion or the loss of topsoil.

3. Be located on a geologic unit or soil that is unstable, or that would become unstable as a result of the project, and potentially result in on- or off-site landslide, lateral spreading, subsidence, liquefaction or collapse.

4. Be located on expansive soil, as defined in Table 18-1-B of the Uniform Building Code (1994), creating substantial risks to life or property.

5. Have soils incapable of adequately supporting the use of septic tanks or alternative waste water disposal systems where sewers are not available for the disposal of waste water.

5.6.4 Impacts

Would the project expose people or structures to potential substantial adverse effects, including the risk of loss, injury, or death involving:

Rupture of a known earthquake fault, as delineated on the most recent Alquist-Priolo Earthquake Fault Zoning Map issued by the State Geologist for the area or based on other substantial evidence of a known fault? Refer to Division of Mines and Geology Special Publication 42.

Potential site ground rupture, as determined by the Leighton and Associates Fault Investigation, is considered moderate to high. Ground rupture due to onsite faults could potentially affect existing and future facilities (such as gas, electrical, water mains, etc.) that traverse fault zones on the site. In order to mitigate for potential impacts associated with seismic ground shaking, mitigation is provided (see *Section 5.6.5, Mitigation Measures*, *Mitigation Measure 5.6-c*).

Strong seismic ground shaking?

The project site is located in seismically active southern California with numerous fault systems in the region. Structures will be designed in accordance with the values and parameters given within the Universal Building Code (UBC) as required by state law. With the incorporation of UBC seismic design parameters in construction of structures on site, the impacts associated with exposure of people to geological hazards is less than significant. These measures are a standard part of the Building Permit process and additional mitigation measures are not required.

Seismic-related ground failure, including liquefaction?

Liquefaction potential analyses and earthquake-induced settlement calculations were performed utilizing the computer program LiquefyPro. Considering the potential ground motions resulting from the design basis ground motion (0.9g) and a maximum moment magnitude event for the

San Jacinto Fault (6.9Mw), the program follows the latest study procedures. Leighton used the boring data, CPT data and groundwater data (perched groundwater table ranging from 5 to 22 feet) as assumptions in the model.

Based on the above-described model, the relatively loose saturated alluvial deposits onsite are considered susceptible to liquefaction hazards. Liquefaction occurs when loose material becomes mobile during a seismic event. In order to compensate for hazards associated with liquefaction, mitigation is provided (see *Section 5.6.5, Mitigation Measures*, Mitigation Measures 5.6-b and 5.6-e). With implementation of these measures, liquefaction potential for the project will be less than significant.

Landslides?

Due to the flat nature of the site and the existing topsoil and Quaternary-aged alluvium, the subject site is not prone to landslide hazards. That said, manufactured slopes that are planned for construction on the site would be susceptible to slope stability hazards. In order to prevent any significant impacts from occurring, mitigation is provided (see *Section 5.6.5, Mitigation Measures*, Mitigation Measure 5.6-f).

Slopes adjacent to severe flow direction changes may be susceptible to increased scour erosion and slope stability. In order to reduce this potential impact to a level below significance, mitigation is provided (see *Section 5.6.5, Mitigation Measures*, Mitigation Measure 5.6-g).

Would the project result in substantial soil erosion or the loss of topsoil?

Short-term erosion effects during the construction phase of the project would be minimized through implementation of the City of San Jacinto construction Best Management Practices (see *Section 5.8.5, Mitigation Measures*, Mitigation Measure 5.8-d)

Would the project be located on a geologic unit or soil that is unstable, or that would become unstable as a result of the project, and potentially result in on- or offsite landslide, lateral spreading, subsidence, liquefaction, or collapse?

The volume change of excavated onsite materials upon recompaction is expected to vary with materials, density, moisture content, location and intended compaction effort. This variance in material could potentially result in shrinkage, which would result in potential subsidence risk. In order to reduce potential impacts to a level below significant, mitigation is provided (see *Section 5.6.5, Mitigation Measures*, Mitigation Measure 5.6-d and 5.6-e).

Many portions of the site are characterized as having unsuitable near surface compressible soils not suitable for structural support. Location of a structure on an unstable geological unit or soil

would be a significant impact; thus, mitigation is provided (see Se*ction 5.6.5 Mitigation Measures,* 5.6-a).

Would the project be located on expansive soil, as defined in Table 18-1-B of the Uniform Building Code (1994), creating substantial risks to life or property?

Expansive soils are those with a significant amount of clay particles that have the ability to shrink or swell depending on water content. The Geotechnical Report indicated that based on limited laboratory testing and visual classification, onsite earth materials generally possess a very low to medium expansion potential; however, high to very high expansive silt and clay materials may be encountered locally during rough grading. Compliance with recommendations for ground preparation as outlined in the February 28, 2005, Leighton and Associates Geotechnical Investigation will reduce risk hazards associated with expansive soils to a less than significant level.

Would the project have soils incapable of adequately supporting the use of septic tanksor alternative wastewater disposal systems where sewers are not available for the disposal of wastewater?

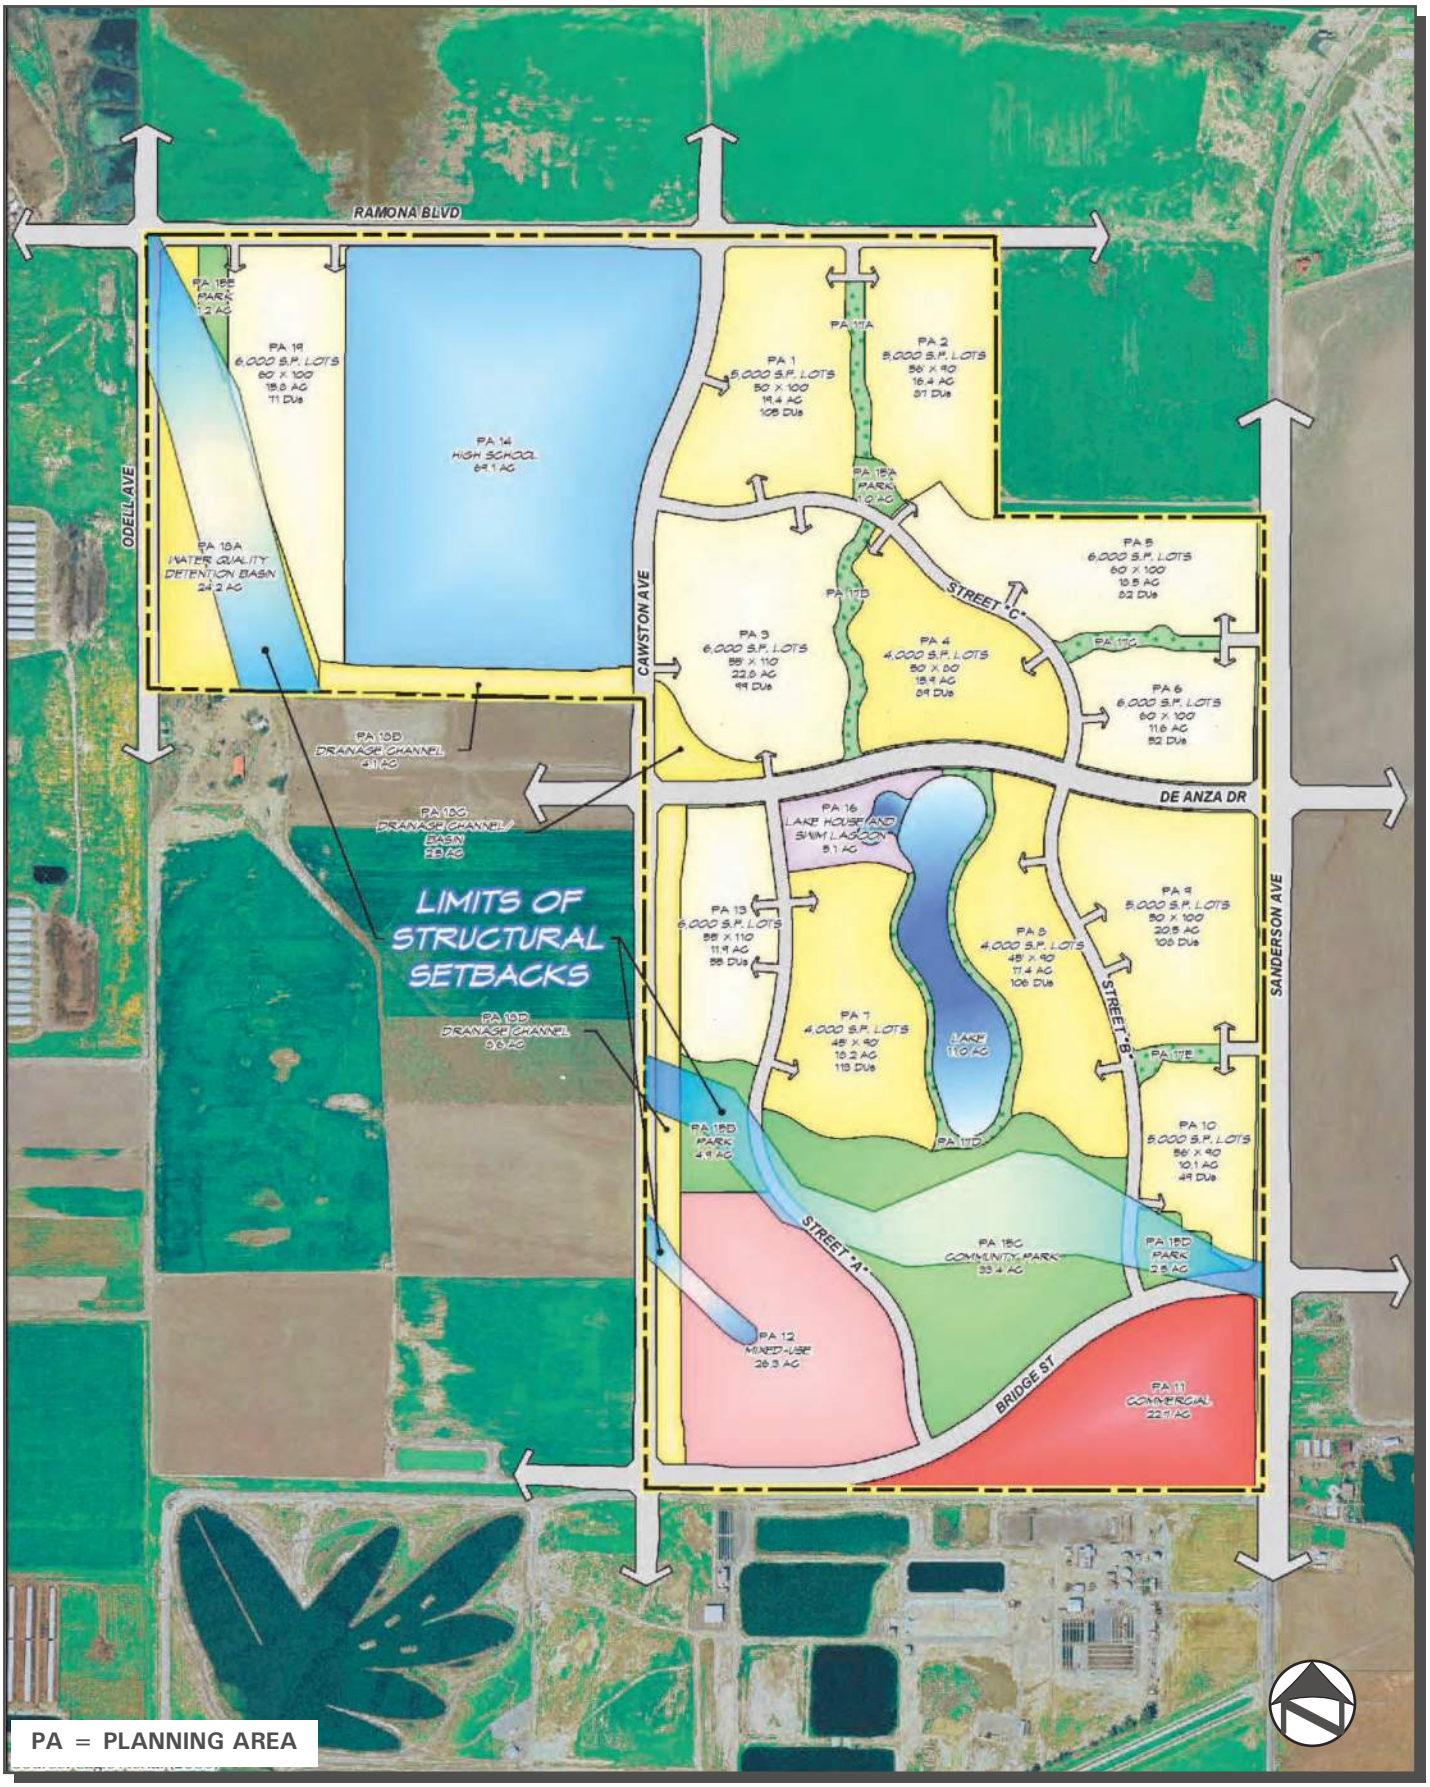
No septic tanks or alternative wastewater disposal systems are proposed as part of the project. As a result, no impact would result.

5.6.5 Mitigation Measures

5.6-a The on-site soils are suitable for reuse as compacted fill, provided they are relatively free of organic materials, debris and oversize materials. The optimum lift thickness to produce a uniformly compacted fill will depend on the type and size of compaction equipment used. In general, fill will be placed in uniform lifts not exceeding 8 inches in thickness. Fill soils will be placed and compacted to a minimum 92 percent relative compaction at a minimum of 2 percent above the optimum moisture content.

Fill slopes shall be overbuilt a minimum of 2 feet and trimmed back to the compacted core or rolled with a weighted sheepsfoot compaction roller as the fill slope height increases in maximum 4-foot increments. Placement and compaction of fill shall be performed in accordance with City grading ordinances and minimum compacted standard under the observation and testing of a qualified geotechnical engineer.

All loosely packed exploration trench backfill shall be removed and recompacted in accordance with project geotechnical guidelines. An engineering geologist shall be present to observe all excavations to confirm limits of faulting. If exposures differ from



anticipated conditions, further investigations and/or additional structural setbacks can be required.

5.6-b To facilitate the grading operations, on-site irrigation water shall be reduced or ceased for a period of 3 to 6 months prior to the start of grading. Further, the contractor will pothole the upper 12 to 14 feet of soil prior to the start of grading operations to determine if shallow groundwater will affect the planned grading.

In localized areas where shallow groundwater conditions exist such that removals cannot be performed to the required depths or where deeper excavations (such as in the proposed "lake" areas) are proposed at or below the existing perched groundwater, methods of localized dewatering will be required including the use of well points and/or interceptor ditch methods. Alternative ground stabilization methods such as deep dynamic compaction shall be required. Deep dynamic compaction is a means of physically compacting the subsurface soils by repeatedly dropping a heavy weight (typically a large concrete block) to densify the underlying soils to a predetermined density. After proposed grading plans are developed, these areas shall be further reviewed by a qualified geotechnical engineer.

5.6-c A structural setback zone of 50 feet on either side of the encountered fault zone, and as much as 75 feet on the "down-block" side shall be observed for structures intended for human occupancy (2,000 hours/year). This preliminary setback zone will be refined as the grading concept is developed and possible additional site studies are performed. The Fault Location Map (Plate 2) within the Fault Investigation shows required preliminary structural setbacks. However, the final setback limits shall be determined during grading or future studies as the fault trace is exposed, identified and surveyed for lateral and vertical location. The setbacks shall be shown on all project plans.

To reduce the effects and magnitude of the earthquake-induced settlements, remedial grading shall occur. Following remedial grading, differential dynamic settlements are anticipated to be approximately 2 inches in a horizontal distance of 40 feet. Additional analysis will be performed by a qualified geotechnical specialist to further refine earthquake-induced settlement. Based on a review of the rough grading plans by a qualified geotechnical specialist, remedial grading requirements will be revised.

SPECIFIC MAP SOURCE: T&B PLANNING CONSULTANTS, May 2009

Villages of San Jacinto EIR

Land Use Plan with Geotechnical Setback Recommendations

FIGURE 5.6-5

INTENTIONALLY LEFT BLANK

To reduce the potential adverse secondary seismic effects, mitigation of compressible alluvial soils to support the planned development at areas such as free-face slopes ("green belt" detention basins, channels etc.), the project perimeter (where removals may be limited by property restraints) and planned lake areas will require additional geotechnical stability design by a qualified geotechnical engineer after project plans are developed.

5.6-d While it is difficult to determine the level of subsidence and shrinkage risk, site grading must include a balance area or ability to adjust import quantities to accommodate some variation. Relative compaction rates must be followed as they appear in the February 28, 2005, Leighton and Associates Technical Report. As stated in the February 28, 2005, Leighton Report, due to the agricultural discing of the surface soils, a subsidence value of 0.2 feet must be applied when evaluating earthwork volumes.

5.6-e To reduce the potential for liquefaction and earthquake-induced settlements at the site, the following guidelines will be implemented. For preliminary design purposes, a minimum removal and recompaction of 10 feet (as measured from finish grade) will be used in cut areas on that portion of the site designated as having a high potential for liquefaction (roughly the northern one third to one half of the site).

In cut areas outside the area designated as high potential for liquefaction, a minimum overexcavation of 5 feet below finish grade must be used. For areas designated as “fill” a minimum removal of 5 feet will be used, provided a minimum total thickness of 10 feet of properly compacted fill is maintained below the lowest adjacent finish grade (including lowest adjacent street elevation). The removal depths for the infrastructure roadways shall be a minimum 5 feet below pavement subgrade. These estimates are for preliminary design planning only and will be revised based on our review of rough grading plans. These preliminary estimates will be revised upon review of the proposed grading concept plan. These alluvial soils must be removed down to medium dense to dense, relatively non-porous alluvium material as determined by the geotechnical consultant. Undercuts will be made 1:1 next to existing roadways that will remain after grading. Cut slopes shall be replaced as properly compacted fill.

The excavated materials will be moisture conditioned or dried back, as appropriate, to achieve the required minimum relative compaction. Saturated soils may need to be dried back or mixed with drier on-site materials and shall be thoroughly mixed prior to fill placement. The resultant excavation will be filled and compacted in this lifts to a minimum 92 percent relative compaction at a minimum of 2 percent above the optimum moisture content. A minimum 90 percent relative compaction may be acceptable in the southern portion of the site. This will be determined during review of rough grading plans.

After completion of the required removal of unsuitable soils, the approved surface will be scarified, moisture conditioned as needed and compacted prior to placing fill. If subgrade conditions at the approved bottoms are wet and "pumping" near the required removal depth, the scarification and moisture conditioning will not be necessary. Stabilization measures where shallow groundwater conditions are expected at or near the required removal depth may include the use of a stabilization fabric and/or coarse gravel/graded rock and gravel. Where shallow groundwater conditions are present, alternative ground improvement guidelines shall be followed (see Mitigation Measure 5.5-b). Further evaluation of these specific areas will be necessary after draft grading plans are prepared.

5.6-f All slopes will be provided with appropriate surface drainage features and landscaped with drought-tolerant, slope-stabilizing vegetation as soon as possible after grading to reduce the potential for erosion. Berms will be provided at the top of fill slopes to direct water away from slope faces. Lot drainage shall be directed such that runoff on slope faces is minimized. Oversteepening of slopes must be avoided during fine grading and building construction. Although not anticipated, if seepage is encountered in slopes, special drainage features may be necessary.

5.6-g For slopes that are will be adjacent to ditches or other water conveyance features, proper protection including rip rap or other slope protection devices as designed by the project civil engineer would be required. Slope stability and the potential for scour shall be required in the design drainage alignment.

5.6.6 Residual Impacts/Level of Significance After Mitigation

The mitigation measures, which include further monitoring of onsite geotechnical risk as grading plans are finalized for a qualified geotechnical engineer, would reduce impacts related to geology and soils. All mitigating geotechnical features shall be designed/implemented pursuant to the Uniform Building Code and State of California seismic engineering standards. These mitigation measures will therefore reduce geotechnical hazards to less than significant levels.

5.7 PALEONTOLOGICAL RESOURCES

5.7.1 Introduction/Methodology

This section presents a discussion of paleontological resources that would be affected by the proposed project and alternative. Paleontological resources are the fossil or trace remains of past life forms, including both vertebrate and invertebrate species, as well as plants. Fossil remains such as bones, teeth, shells, leaves, etc. are found in the geologic deposits (formations) within which they were originally buried. The geologic composition of an area; therefore enables scientists to evaluate the potential for resources to occur, based on knowledge of resources that have been uncovered from similar geologic formations elsewhere.

Existing condition information is derived from the February 28, 2005, Leighton and Associates, Inc. Preliminary Geotechnical Investigation for the Villages of San Jacinto project. This report is included as *Appendix F* to this EIR. Methods utilized in the February 28, 2005, Leighton Report are contained therein. Paleontological sensitivity data was obtained from the 2003 Riverside County General Plan Update Multipurpose Open Space Element.

5.7.2 Existing Conditions

Sediments derived from the San Jacinto River have been deposited across the river valley. The sediment thickness is thought to be highly variable with a minimum thickness of 500+ feet in the southwest portion of the valley. Paleoeustuary silts and sands, Quaternary-aged terrace deposits and fanglomerates flank major abandoned drainage channels and the base of mountain slopes. Near the City of San Jacinto, a boring excavated northeast of the Casa-Loma Fault segment did not reach basement rocks to the depth explored of 1,430 feet. In general, seismic and gravity surveys indicate that approximately 6,500 feet to 7,900 feet of alluvial sediment overlie the basement bedrock in the valley.

As indicated on Figure OS-8 of the 2003 Riverside County General Plan Update Multipurpose Open Space Element, the project is located within an area characterized as having a high likelihood of supporting fossils (see *Figure 5.7-1, Paleontological Sensitivity*). The San Jacinto Valley is designated as "High B (Hb)" which means a resource's probability to occur is based on the occurrence of fossils at a specified depth below the surface. This category indicates that fossils are likely to be encountered at or below four feet of depth and may be impacted during excavation by construction activities (County of Riverside, 2003, pg. OS-36 to OS-37, Figure OS-8).

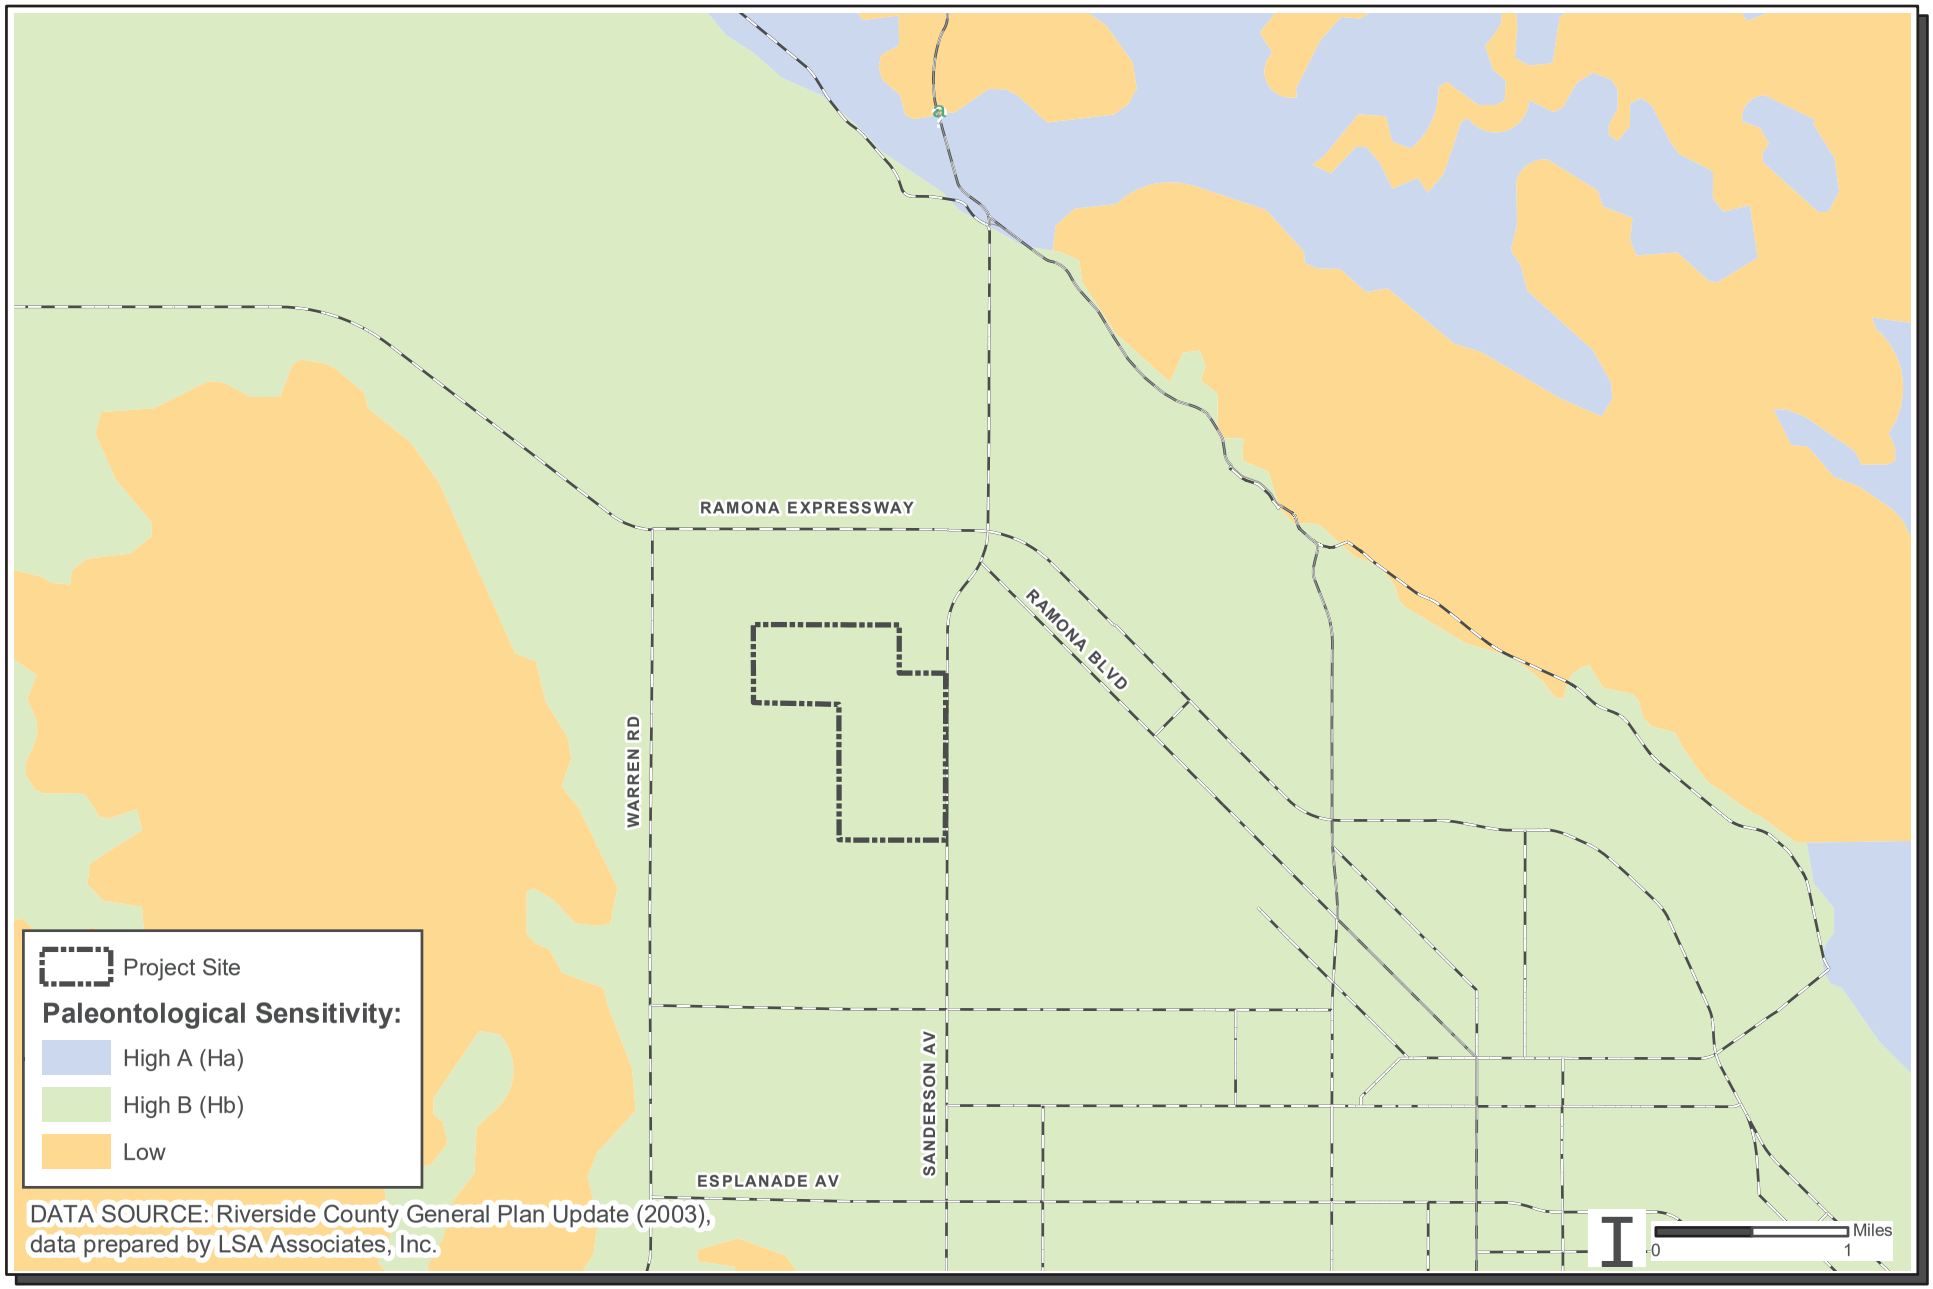
5.7.3 Significance Criteria

Based on the criteria identified in Appendix G of the CEQA Guidelines, the proposed project would have a significant impact on paleontological resources if it:

1. Directly or indirectly destroy a unique paleontological resource or site or unique geologic feature.

5.7.4 Impacts

Would the project directly or indirectly destroy a unique paleontological resource or site or unique geologic feature?



Since the proposed project lies within a geologic formation with high resource bearing potential and the project would necessitate recompaction of potential fossil bearing alluvium, impacts to paleontological resources are considered to be significant. Impacts to paleontological resources could occur during excavation and site development when geologic formations that have resource bearing potential are disturbed. Impacts would occur when fossils are physically destroyed by such activities. In order to reduce potential construction-related impacts to paleontological resources, mitigation is provided (see *Section 5.7.5, Mitigation Measures*, Mitigation Measure 5.7-a).

5.7.5 Mitigation Measures

5.7-a Prior to beginning any excavation work, the developer or its contractor shall demonstrate that a qualified paleontologist has been retained to carry out a paleontological resources mitigation program. A paleontological monitor shall be on site at all times during grading activities that disturb non-undocumented fill soils or formations. If fossils are discovered, the paleontologist or paleontological monitor shall have the authority to halt construction in the immediate area of discovery until such a time that a complete assessment of the resources can be conducted. If resources are found that are determined to be significant, the paleontological monitor shall direct activities to recover the resources. Prepared fossils, along with copies of all pertinent field notes, photos and maps shall be deposited in a scientific institution with paleontological collections, such as the San Bernardino County Museum.

5.7.6 Residual Impacts/Level of Significance after Mitigation

With the implementation of the construction monitoring program (outlined as Mitigation Measure 5.7-a, above), impacts to paleontological resources would not be significant.

Villages of San Jacinto EIR

FIGURE

INTENTIONALLY LEFT BLANK

5.8 WATER QUALITY AND HYDROLOGY

5.8.1 Introduction/Methodology

This section consists of a summary of existing hydrologic conditions, anticipated impacts related to these conditions, and mitigation measures required to reduce these impacts to a level below significance. A residual impact statement has been included to characterize the level of significance after applied mitigation measures.

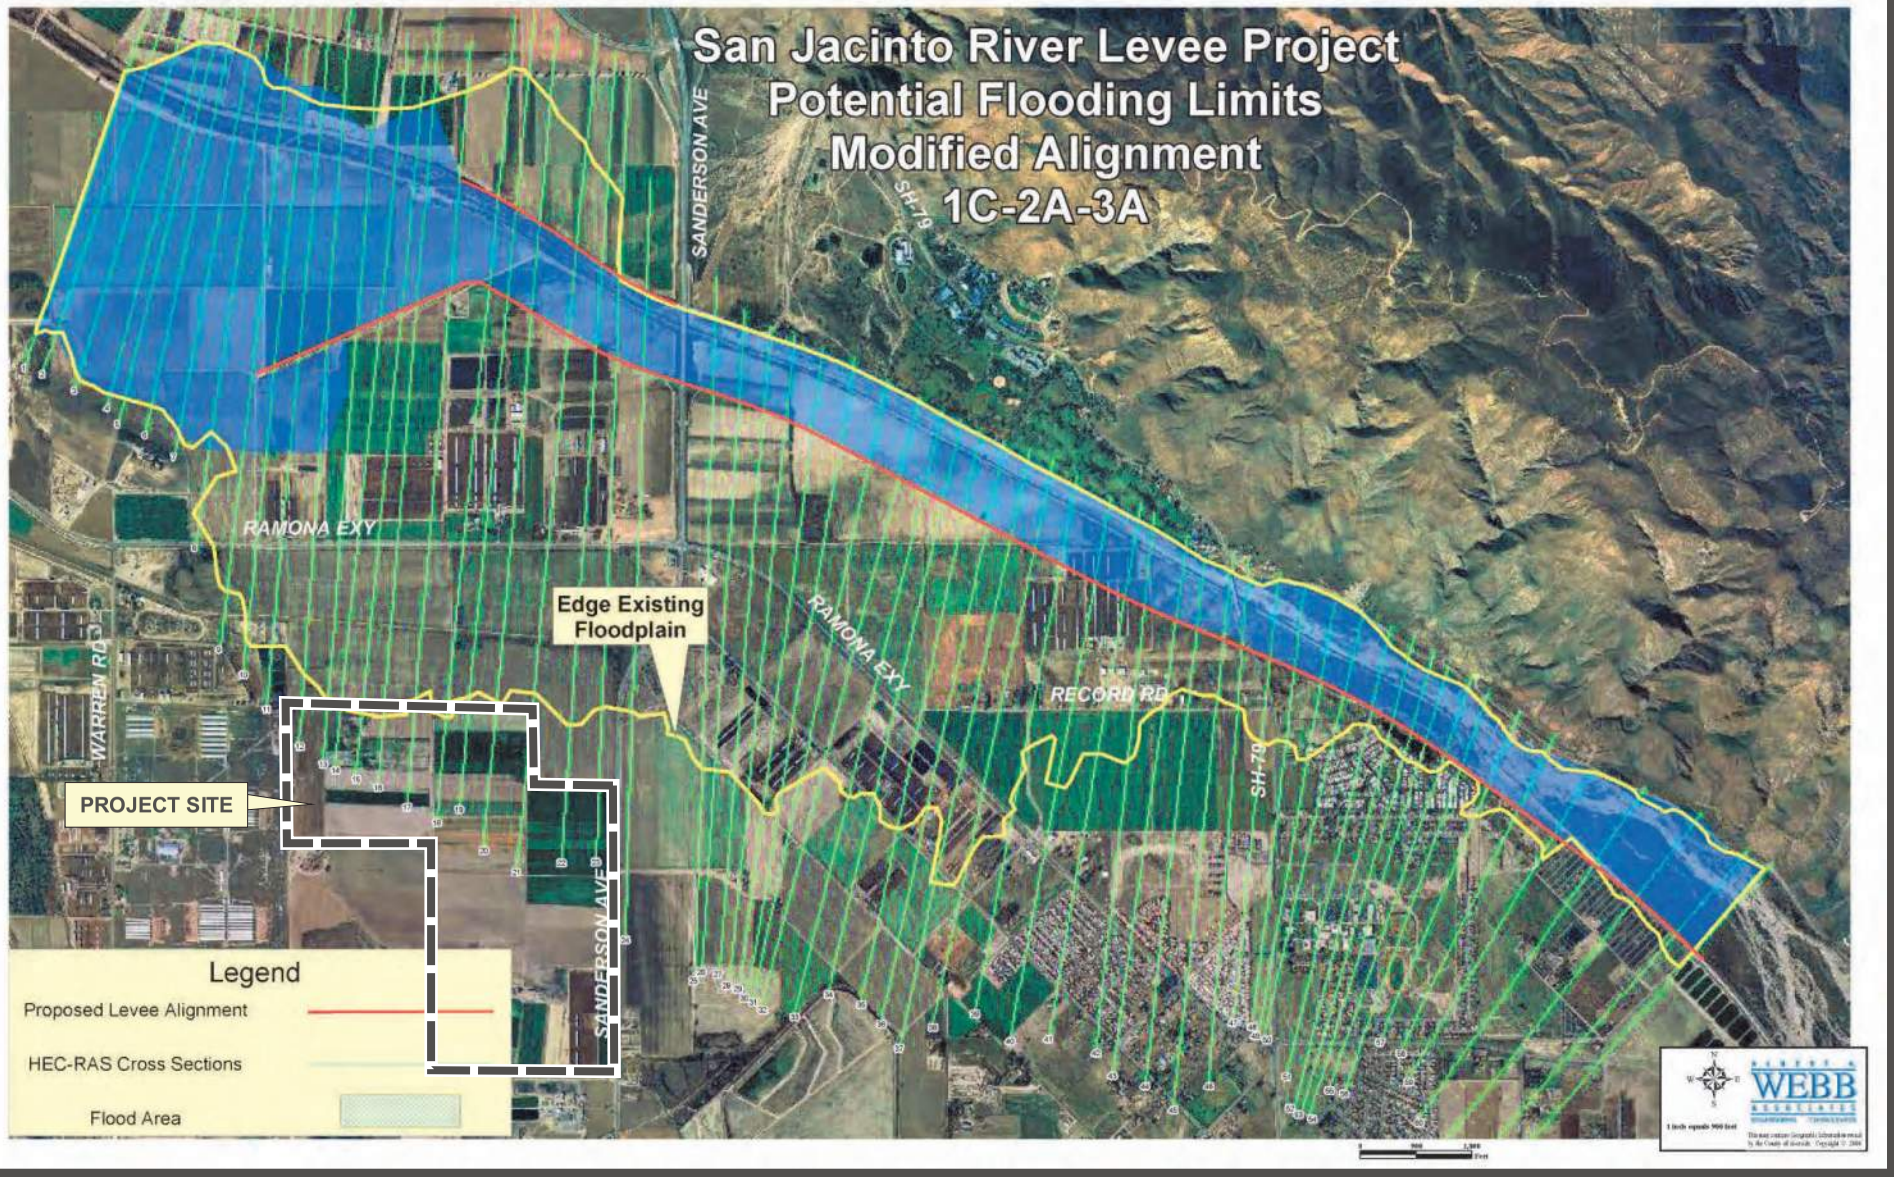
This analysis is based on information contained in the February 2009 *Villages of San Jacinto Specific Plan, Drainage Plan* by T&B Planning Consultants; the May 2006 *Preliminary Drainage Study for Tentative Tract Map 34081* by RBF Consulting; the August 2006 *Phase 1 and 2 Preliminary Drainage Study for Tentative Tract Map 34081* by RBF Consulting; the January 15, 2007, *Summary Preliminary Drainage Analysis for TTM 34081 Phases 1, 1A, 1B & 1C* by RBF (included as *Appendix G* to this EIR); and the February 23, 2009, *Preliminary Hydrology and Hydraulics Study for the Villages of San Jacinto* by JLC Engineering & Consulting Inc. Floodplain resource information was obtained through the September 7, 2006, letter from RBF to Riverside County Flood Control and Water Conservation District. Water quality management information was obtained from the February 23, 2009, *Preliminary Hydrology and Hydraulics Study* referenced above and the *Lake Preliminary Design Report* (Pacific Aquascape, Inc. March 2009). Additional hydrologic resource setting and existing conditions information was used from the February 28, 2005, Leighton and Associates Geotechnical Investigation for the proposed project (included in *Appendix F* to this EIR); discussions with Leighton and Associates geotechnical staff; and publications by the Santa Ana Regional Water Quality Control Board (RWQCB) (1995, 2003, 2004). Once existing condition information was summarized, the City of San Jacinto Significance Thresholds, specifically Hydrology and Water Quality Resource Thresholds, were used to determine if hydrologic impacts were considered significant from a CEQA perspective. Mitigation measures were developed in part by recommendations in the February 2009 Villages of San Jacinto Specific Plan, Drainage Plan Report by T&B Planning Consultants and experience with past projects of a similar size and character.

5.8.2 Existing Conditions

The San Jacinto and broader Inland Empire climate is mild. Winters are characterized as mild and sometimes cool, springs can be rainy, and the summer and fall hot and dry. The San Jacinto area climate is characterized by relatively low rainfall, with warm summers and mild winters. Annual precipitation averages about 13 inches, with over 70% of that falling between December and March. Average monthly temperatures range from a high of 98° Fahrenheit in August to a low of 37° Fahrenheit in December (City-Data.com, Accessed April 30, 2009).

The San Jacinto River is the dominant hydrologic feature of the central western Riverside County area. Rainwater and urban runoff drain through a series of reservoirs, canyons, and/or storm drain facilities into this drainage system. This hydrologic feature runs along the northern and eastern edge of the City (see *Figure 5.8-1, Existing Hydrologic Features*).

5.8.2.1 Surface Water



The main surface hydrologic feature of the San Jacinto Valley is the San Jacinto River. This waterway is a natural channel that has been disturbed by historical filling and farming activities. This river flows from east to west and serves as the main drainage point for precipitation runoff from higher elevations to the east and urban runoff throughout the watershed.

Within the river valley, various channels and ephemeral creeks feed the river system. This watercourse is located approximately 1 mile northeast of the project site. General off-site drainage occurs through a northern sheet-flow pattern off the project site toward the San Jacinto River. Surface water runoff often ponds on site and throughout the river plain to form an alkali playa hydrologic feature. Currently, on-site water drains in a sheet flow manner to the north toward the San Jacinto River. On-site irrigation channels also assist in drainage of the site.

5.8.2.2 Groundwater

Groundwater is defined as subsurface water that exists in soils and geologic formations that are fully saturated. The water table is considered to be the top of the saturated zone. Groundwater bearing formations sufficiently permeable to transmit and yield significant quantities of water are called aquifers. The principal groundwater basins in the San Jacinto Region are the Lakeview/Hemet-North, San Jacinto-Upper Pressure, and Hemet-South. The project site straddles the Lakeview/Hemet-North basin to the west and the San Jacinto-Upper Pressure basin to the east. The San Jacinto River had historically kept all the groundwater basins in that part of the region full. Now, there is essentially no surface flow beyond the mouth of the canyon, where it exits the mountains; the riverbed is typically dry (State of California 1995, p. 1-5).

Similar to most Riverside County rivers, the San Jacinto River is supported by a groundwater basin. Groundwater was locally encountered on the site at depths between 5 and 40 feet below existing ground surface elevations. It is suspected that groundwater may be as deep as 200 feet below ground surface on the project site. The groundwater table likely fluctuates seasonally in response to long periods of heavy rainfall or groundwater withdrawal (Leighton 2005, p. 7).

Villages of San Jacinto EIR

Existing Hydrologic Features

FIGURE 5.8-1

INTENTIONALLY LEFT BLANK

5.8.2.3 Flooding

As depicted on *Figure 5.8-1, Existing Hydrologic Features*, the northwest corner of the project is located within Zone A of the San Jacinto River, as mapped by the Federal Emergency Management Agency (FEMA). Zone A is defined as the area of the 100-year floodplain with base flood elevations and flood hazard factors not determined.

The San Jacinto River Valley has a very unique flood flow regime. Flood flows every 5 or 10 years have contributed to the broad, shallow "Mystic Lake" in the riverbed north of the City. The shallow, periodic flooding of this river has contributed to the wildlife and alkali-playa-dependent plant species that characterize the area.

5.8.2.4 Water Quality

Water quality refers to the effect of natural and human activities on the composition of water. Water quality is expressed in terms of measurable physical and chemical qualities that can be related to planned water use. In general, stormwater can potentially contain a host of pollutants, such as trash and debris, bacteria and viruses, oil and grease, sediments, nutrients, metals, and toxic chemicals. These contaminants can adversely affect receiving and coastal waters, flora and fauna, and public health. Water quality issues are especially prevalent during rainy periods; however, due to the amount of urban runoff that is transferred to the storm drain and natural drainage system, pollution is a problem year-round.

Regulatory Background

Several important federal and state legislative actions have an impact on how water quality is measured, controlled, and addressed during the planning process. Important legislation and regulatory mechanisms are therefore outlined below.

Federal Water Pollution Control Act (Clean Water Act)

The basic federal law regulating surface water quality control is referred to as the Federal Water Pollution Control Act of 1972, commonly referred to as the Clean Water Act. The main objective of the Clean Water Act is to "restore and maintain the chemical, physical and biological integrity of the Nation's waters and to make all waters fishable and swimmable." The Clean Water Act established seven goals and guidelines for water quality, including the elimination of pollutants to navigable waters by 1985, provision of quality water to allow for propagation of fish and other marine life, prohibition of pollutants in toxic amounts, provision of financial assistance to waste treatment management plans, development of technology necessary to carry out goals, and development and implementation of programs for control of non-point source pollution. Clean

Water Act provisions have been written in conjunction with applicable plans and policies of the federal Endangered Species Act and the National Environmental Policy Act.

The Clean Water Act, in part, establishes requirements for state water quality planning, management, and implementation with regard to surface waters. These requirements call for the restoration and maintenance of chemical, physical, and biological integrity of state waters; attainment of a level of water quality that provides for the protection and propagation of fish, shellfish, and wildlife and recreation in and on the water; and consideration of water resources for state water supplies and other beneficial uses. The Clean Water Act requires that the goals and guidelines established by varying state agencies be reviewed on a triennial basis. This process involves public hearings at least once every 3 years for the purpose of review and/or revisions (State of California 1995, p. 1-2).

Other provisions of the Clean Water Act related to basin planning include Section 208, which authorizes the preparation of waste treatment management plans, and Section 319, which mandates specific actions for the control of pollution from non-point sources. 1987 amendments to the Clean Water Act identified the importance of non-point source pollutants and their impact on local water quality. As stated in the Water Quality Control Plan for the Santa Ana River Basin (State of California 1995), non-point source pollutants represent the greatest threat to water quality. Non-point source pollutants are often chemicals from lawns or gardens, automobile residues, urban runoff, or household cleaning agents or compounds. Most non-point source pollutants enter the water supply in large quantities and sudden surges, largely due to storm events. Control of this type of pollution source has proven to be difficult. Because the release of a non-point source pollutant is exempt from National Pollution Discharge Elimination System (NPDES) regulations, the RWQCB has more recently focused on non-point source pollution issues. The RWQCB has encouraged all community members to use best management practices (BMPs) to eliminate or reduce non-point source pollution.

National Pollution Discharge Elimination System (NPDES)

NPDES, established under the Clean Water Act, regulates the discharge of pollutants from point sources into regional water resources. The NPDES permit regulates discharges of wastes for the purpose of limiting the quantity of pollutants and volume of waste discharged to surface waters. NPDES permits contain prerequisite conditions that must be met by dischargers to ensure protection of the receiving water. Any agency or private party proposing to discharge pollutants into surface waters must submit a report of waste discharge at least 180 days in advance of the planned date of release. Concurrence with pollution elimination levels and approval of the report of waste discharge would culminate in the granting of an NPDES permit. Responsibility of enforcement of NPDES guidelines and permits falls within jurisdiction of the RWQCB (Region 8 for the San Jacinto Basin), and is subject to review by the Environmental Protection

Agency (EPA) Regional Administrator (EPA Region IX, San Francisco Office) (State of California 1995, p. 5-2).

The EPA has published NPDES permit application requirements for municipal, industrial, and construction stormwater discharges under the urban runoff management strategy. The application requirements for municipalities were directed at municipalities that own and operate separate storm drain systems servicing populations of 100,000 or more or that contribute significant pollutants to waters of the United States and require such agencies to obtain coverage under municipal stormwater NPDES permits. Municipalities were required to develop and implement an urban runoff management program to address activities to reduce pollutants in urban runoff and stormwater discharges that were contributing a substantial pollutant load to their systems.

In order to control water quality, the State Water Resources Control Board has organized basin plans for all drainage systems within California. Goals and plans set forth in the Water Quality Control Plan for the Santa Ana River Basin (State of California 1995) are carried out through the use of the NPDES permitting and monitoring system.

303(d) Status Listing

Under Section 303(d) of the 1972 Clean Water Act, states, territories, and authorized tribes are required to develop a list of water quality limited segments. These waters on the list do not meet water quality standards, even after point sources of pollution have installed the minimum required levels of pollution control technology. The law requires that these jurisdictions establish priority rankings for water on the lists and develop action plans, called Total Maximum Daily Loads (TMDL), to improve water quality.

California Water Code

The California Water Code is the principal policy that governs the use of water resources within the State of California. This code controls water rights, policies governing the construction and management of dams and reservoirs, flood control, conservation, development and utilization of state water resources, water quality protection, and management and management of water-oriented agencies (State of California 1995, pp. 1-1 to 1-2). The water quality provisions set forth in the California Water Code have been written to supplement certain provisions of the California Health and Safety Code, Public Resources Code, Fish and Game Code, Food and Agriculture Code, Government Code, Harbors and Navigation Code, California Environmental Quality Act, and the California Endangered Species Act.

Porter-Cologne Water Quality Control Act

Division 7 of the California Water Code, commonly referred to as the Porter-Cologne Water Quality Control Act, is the principal mechanism for water quality control within California. This act establishes a regulatory program to protect water quality and beneficial uses of all state waters. The Porter-Cologne Act established the State Water Resources Control Board and RWQCB as principal state agencies responsible for water quality control. Water quality of the Santa Ana River Basin is controlled by Region 8 Regional Water Quality Control Board of the State Water Resources Control Board (State of California 1995, p. 1-1).

Relevant Plans and Policies

Water Quality Control Plan for the Santa Ana River Basin (Region 8)

The federal Clean Water Act, and, specifically the NPDES program as well as the California Water Code (specifically, the Porter-Cologne Water Quality Control Act) require that the Regional Water Quality Control Board adopt a water quality control plan to guide and coordinate the management of water quality in the Region. The Santa Ana River Basin Plan's purpose is to (1) designate beneficial uses of the Region's surface water and groundwater, (2) designate water quality objectives for the reasonable protection of those uses, and (3) establish an implementation plan to achieve the objectives. This basin plan was adopted in 1995 and has been subject to several amendments over the last 10 years. This plan outlines water quality planning guidelines for the Upper and Lower Santa Ana Region watersheds, the San Jacinto River watershed and several other small drainage areas in southwestern San Bernardino County, western Riverside County, and northwestern Orange County (State of California, Santa Ana RWQCB 1995).

The Villages of San Jacinto project is located approximately 1 mile southwest of the San Jacinto River. The Santa Ana River Basin Plan divides the County into "Hydrologic Units" (HU). Each HU has a "Hydrologic Area" (HA). Each HA can be divided into "Hydrologic Sub Areas" (HSAs). The project is located within the San Jacinto River Basin HU and the San Jacinto River HA. The project is located near Reach 4 - Nuevo Road to North–South Mid-Section Line (T4S/R1W-S8). Beneficial uses have been identified for each of the water bodies the project could potentially impact (State of California 1995, p. 3-21).

Inland Surface Waters

San Jacinto River HA: Beneficial uses include Municipal and intermittent beneficial uses include Agricultural, Groundwater, Recreation (1), Recreation (2), Warm Freshwater Habitat and Wildlife Habitat (State of California 1995, p. 3-21).

The Basin Plan identifies Water Quality Objectives for each water body within the Santa Ana River Watershed. The project is located within an inland surface stream area, specifically Reach 4 of the San Jacinto River. Guidelines pertain to algae, un-ionized ammonia, acute (1-hour) ammonia-nitrogen, fecal coliform bacteria, boron, chemical oxygen demand, chloride, residual chlorine, color, total filterable dissolved solids, floatables, fluoride, hardness, inorganic nitrogen, metals, methylene blue-activated substances, nitrate, total inorganic nitrogen, oil and grease, total dissolved oxygen, pH, radioactivity, sodium, suspended and settleable solids, sulfate, sulfides, surfactants, taste and odor, temperature, toxic substances, and turbidity. The Basin Plan mandates that all waters of the region shall be maintained in accordance with each pollutant-specific objective and shall not be exceeded as a result of controllable water quality factors (State of California 1995, p. 4-34)

Groundwater

San Jacinto-Upper Pressure and Hemet-South: Beneficial uses include Municipal, Agricultural, Industrial, and Industrial Process Supply (State of California 1995, p. 3-27 and Figure 3-4).

The Basin Plan identifies Water Quality Objectives for each groundwater body within the Santa Ana River Watershed. The project is located within a groundwater area, specifically the San Jacinto – Upper Pressure basin. The Basin Plan quantifies limits or designates guidelines for discharge into the San Jacinto River. Guidelines pertain to arsenic, fecal coliform bacteria, boron, barium, chloride, color, cyanide, total dissolved solids, fluoride, hardness, metals, methylene blue-activated bustances, nitrate, oil and grease, pH, radioactivity, sodium, sulfate, taste and odor, total inorganic nitrogen, and toxic substances. The Basin Plan mandates that all waters of the region shall be maintained in accordance with each pollutant-specific objective and shall not be exceeded as a result of controllable water quality factors (State of California 1995, pp. 4-11 to 4-13, 4-34).

Lake Elsinore and Canyon Lake Nutrient TMDL Allocation and Implementation Plan

According to the California 2002 303(d) list (approved by the USEPA on July 2003) published by the Santa Ana RWQCB, the San Jacinto River is not listed as an impaired water body. That said, Lake Elsinore, which is located downstream of the project site and is fed by the San Jacinto River, is listed on the 303(d) list as an impaired water body. The pollutants of concern in Lake Elsinore include nutrients, organic enrichment/low dissolved oxygen, sedimentation/siltation, and other pollutants where toxicity is unknown. Watershed-wide waste discharge requirements for discharges of stormwater runoff associated with new developments have been adopted for the San Jacinto River Watershed. These discharge objectives include the following:

NPDES Stormwater Discharge Construction Permit (Water Quality Order 99-08-DWQ)

Section 402 of the Clean Water Act establishes a framework for regulating municipal and industrial stormwater discharges under the NPDES program. This permit regulates stormwater runoff from construction sites where clearing; grading; or disturbances to the ground, such as stockpiling or excavation that results in soil disturbances of at least 1 acre of total land area, occurs.

5.8.3 Significance Criteria

Based on the criteria identified in Appendix G of the CEQA Guidelines, the proposed project would have a significant impact on water resources and water quality if it:

1. Violates any water quality standards or waste discharge requirements.
2. Substantially depletes groundwater supplies or interferes substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level (e.g., the production rate of pre-existing nearby wells would drop to a level that would not support existing land uses or planned uses for which permits have been granted).
3. Substantially alters the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, in a manner that would result in substantial erosion or siltation on- or off-site.
4. Creates or contributes runoff water that would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources or polluted runoff.
5. Places housing within a 100-year flood hazard area as mapped on a federal Flood Hazard Boundary or Flood Insurance Rate Map or other flood hazard delineation map.
6. Place within a 100-year flood hazard area structures which would impede or redirect flows.
7. Exposes people or structures to a significant risk of loss, injury, or death involving flooding, including flooding as a result of the failure of a levee or dam.
8. Otherwise substantially degrades water quality.

5.8.4 Impacts

Would the project violate any water quality standards or waste discharge requirements?

Perched groundwater was encountered at multiple depths below the surface, as shallow as 5 feet and as deep as 22 feet. Regional groundwater is anticipated below 150 feet and is likely to occur

as much as 200 feet below grade. However, groundwater can be expected to fluctuate seasonally within the subject site and during periods of heavy regional rainfall or groundwater withdrawal by the local residences, agricultural developments, and water utility companies. During drought conditions, groundwater levels could temporarily deepen significantly.

The project would not impact regional groundwater (Leighton 2006). All lake and drainage features on site would be constructed so they are above the regional groundwater table so as to prevent intermixing of ground and surface waters. That said, it is possible that, during project construction, perched groundwater may be encountered. In order to avoid potential impacts to regional groundwater resources in the San Jacinto River Valley, mitigation is provided (see *Section 5.8.5, Mitigation Measures,* Mitigation Measure 5.8-b).

Construction Impacts

Development of the proposed project may result in an increase in pollutant load due to sedimentation. Sediments are soils or other surficial materials eroded and then transported or deposited by the action of wind, water, or gravity. Sediment from erosion, primarily during construction, is quite often a major project pollutant of concern. A potentially significant impact could occur during construction related to sedimentation; therefore, mitigation is provided (see *Section 5.8.5, Mitigation Measures,* Mitigation Measures 5.8-d and 5.8-e).

As indicated above, groundwater may be encountered during construction. In order to prevent impacts to groundwater resources, mitigation is provided (see *Section 5.8.5, Mitigation Measures,* Mitigation Measure 5.8-b).

Operational Impacts

Based upon guidelines within the Riverside County Flood Control & Water Conservation District (RCFC&WCD) BMP Handbook and the Santa Ana RWQCB General Permit for Riverside County, the proposed development must treat potential contaminants produced and associated with the proposed land use types within the project site. As a result, a water quality extended detention basin is being proposed to provide water quality treatment for the runoff emanating from the project site. The volume calculations for the water quality basins are based upon the method included in the RCFC&WCD BMP Handbook. A water quality/extended detention basin is a permanent basin sized to detain and slowly release the design volume of stormwater, allowing particles and associated pollutants to settle out. An inlet forebay section and inlet energy dissipater will minimize erosion from entering flows, while erosion protection at the outlet prevents damage from existing flows. The bottom of the basin slopes toward the outlet and a low flow channel conveys incidental flows directly to the outlet end of the basin. The basin should utilize vegetated earth in order to allow some infiltration to occur, although highly pervious soils may require an impermeable liner to prevent groundwater contamination. Proper

turf management is also required to ensure that the vegetation does not contribute to water pollution through pesticides, herbicides, or fertilizers. The City of San Jacinto will maintain all aspects of the basin pertaining to water quality. RCFC&WCD will maintain all aspects of the basin that pertain to detention.

Lake Preliminary Design Report

This report (Pacific Aquascape, Inc. 2009) discusses safety features for the proposed lake shoreline, water depth and temperature, and treatment of runoff and water quality management. The treatment process involves reduced concentration of dissolved pollutants, nutrients, and salts through flushing of the lake water volume by utilizing the lake as the irrigation supply source; reduction of nutrient concentrations from inflows, nitrogen, and phosphorous; prevention of algae blooms by using constructed gravel biofilter beds that utilizes "biological filtration"; and maintaining oxygen levels through aeration promoting oxygen exchange to prevent anaerobic conditions, which allows natural process to occur, such as denitrification for removal of nitrogen. The lake operation and maintenance program also includes routine debris removal, algae control, aquatic weed control, pump maintenance, and biofilter maintenance. These processes ensure continued aesthetic appeal and desirable water quality as well as control of vectors, such as mosquitoes and flies

Agricultural Operations

The current and previous land uses on the project site generate nitrogen and phosphorous, which may have an impact on existing on-site and off-site water quality. Due to the elimination of agriculture, the project site will likely result in a beneficial impact due to a reduction in nitrogen and phosphorous.

Pollutants of Concern

Due to the intensification of land uses on the site, in combination with an increase in impervious surfaces, the project may result in potentially significant impacts to water quality attributable to urban pollutants contained in stormwater runoff. The constituents described below commonly are found on similar developments as a result of urban runoff and could, therefore, affect the proposed project's water quality. The development of a final Water Quality Management Plan (WQMP) as specified in Mitigation Measure 5.8-f, ensures that overall reduction is achieved for all pollutants listed below. An extended detention basin and vegetated swale (vegetated channel) as proposed, has low to high removal effectiveness for all pollutants per the *Riverside County Stormwater Quality BMP Design Handbook* (RCFC&WCD, July 21, 2006). Other project specific measures are proposed which will ensure that the project will not violate any water quality standards or waste discharge requirements.

Nutrients

Nutrients are inorganic substances, such as nitrogen and phosphorus. The primary sources of nutrients in urban runoff are fertilizers and eroded soils. Due principally to the type of land use, the project is anticipated to result in the transport of fertilizers from landscape areas by stormwater or water from irrigated sprinklers and wash down activities, resulting in a potentially significant impact. In order to reduce this potential impact, mitigation is provided (see *Section 5.8.5, Mitigation Measures*, Mitigation Measure 5.8-f).

Heavy Metals

metals are raw material components in non-metal products, such as fuels, adhesives, paints, and other coatings. Under the proposed project, it is anticipated that heavy metals from vehicles on parking lots and streets may be transported to the storm drain system, resulting in a potentially significant impact (see *Section 5.8.5, Mitigation Measures*, Mitigation Measure 5.8-f).

Organic Compounds

Commercially available or naturally occurring carbon-based organic compounds are found in pesticides, solvents, and hydrocarbons. Landscaping associated with the proposed project may result in release of organic compounds, therefore mitigation is provided (see *Section 5.8.5, Mitigation Measures*, Mitigation Measure 5.8-f).

Trash and Debris

The introduction of a suburban population to the area will contribute to an increase in trash and debris pollution, which will result in a potentially significant impact. In order to reduce potentially significant impacts, mitigation is provided (see *Section 5.8.5, Mitigation Measures*, Mitigation Measure 5.8-f).

Oxygen-Demanding Substances

Biodegradable organic materials on site could react with dissolved oxygen in the water to form other compounds. It is anticipated that an increase in population in the area would result in a likely increase of oxygen-demanding substances in urban runoff, therefore creating a significant impact. In order to reduce this potential impact, mitigation is provided (see *Section 5.8.5, Mitigation Measures*, Mitigation Measure 5.8-f).

Oil and Grease

Oil and grease are characterized as high-molecular-weight organic compounds. The primary source of oil and grease of concern to the proposed project would be leaky cars. Because of their

respective increase in parking facilities, it is anticipated that the mixed-use, commercial, school, and public park uses would result in potentially significant impacts related to oil and grease. In order to reduce this potential impact, mitigation is provided (see *Section 5.8.5, Mitigation Measures*, Mitigation Measure 5.8-f).

Bacteria and Viruses

Pathogens such as bacteria and viruses are typically caused by the transport of animal or human fecal wastes from the watershed primarily through improper or non-disposal of pet wastes. Water, containing excessive bacteria and viruses can alter the aquatic habitat and create a harmful environment for humans and aquatic life. Also, the decomposition of excess organic waste causes increased growth of undesirable organisms in the water. In order to compensate for this potentially significant impact, mitigation is provided (see *Section 5.8.5, Mitigation Measures*, Mitigation Measure 5.8-f).

Pesticides

Herbicides used for controlling nuisance plant growth are a potential source of pollutants. Because the project will introduce new landscaping to the project site, the introduction of herbicides into stormwater runoff is considered a potentially significant impact. In order to reduce this potentially significant impact, mitigation is provided (see *Section 5.8.5, Mitigation Measures*, Mitigation Measure 5.8-f).

Would the project substantially deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level (e.g., the production rate of pre-existing nearby wells would drop to a level that would not support existing land uses or planned uses for which permits have been granted)?

The Water Supply Assessment Report prepared for the project (*Appendix K*) indicates that the total projected water demand for the proposed development would remain within the limits of the projected demand of the Eastern Municipal Water District's Urban Water Management Plan 2000 (refer to *Section 5.12.8* for a detailed discussion of domestic water supply).

The project would result in an increase in impervious surfaces due to the change from an existing agricultural operation (which supports natural percolation) to that of a suburban housing/commercial/retail development (which will support pavement and other impervious surfaces). Although the project would not result in the exact same local groundwater recharge characteristics, the project drainage plan would facilitate complete retention/detention of water onsite to mirror pre-development flows. Therefore, during weather events, water will be directed to the urban drainage system which will collect at the northwest of the site in a detention basin.

This basin will result in the percolation or evaporation of all onsite water which would in effect help mirror existing, pre-development groundwater recharge.

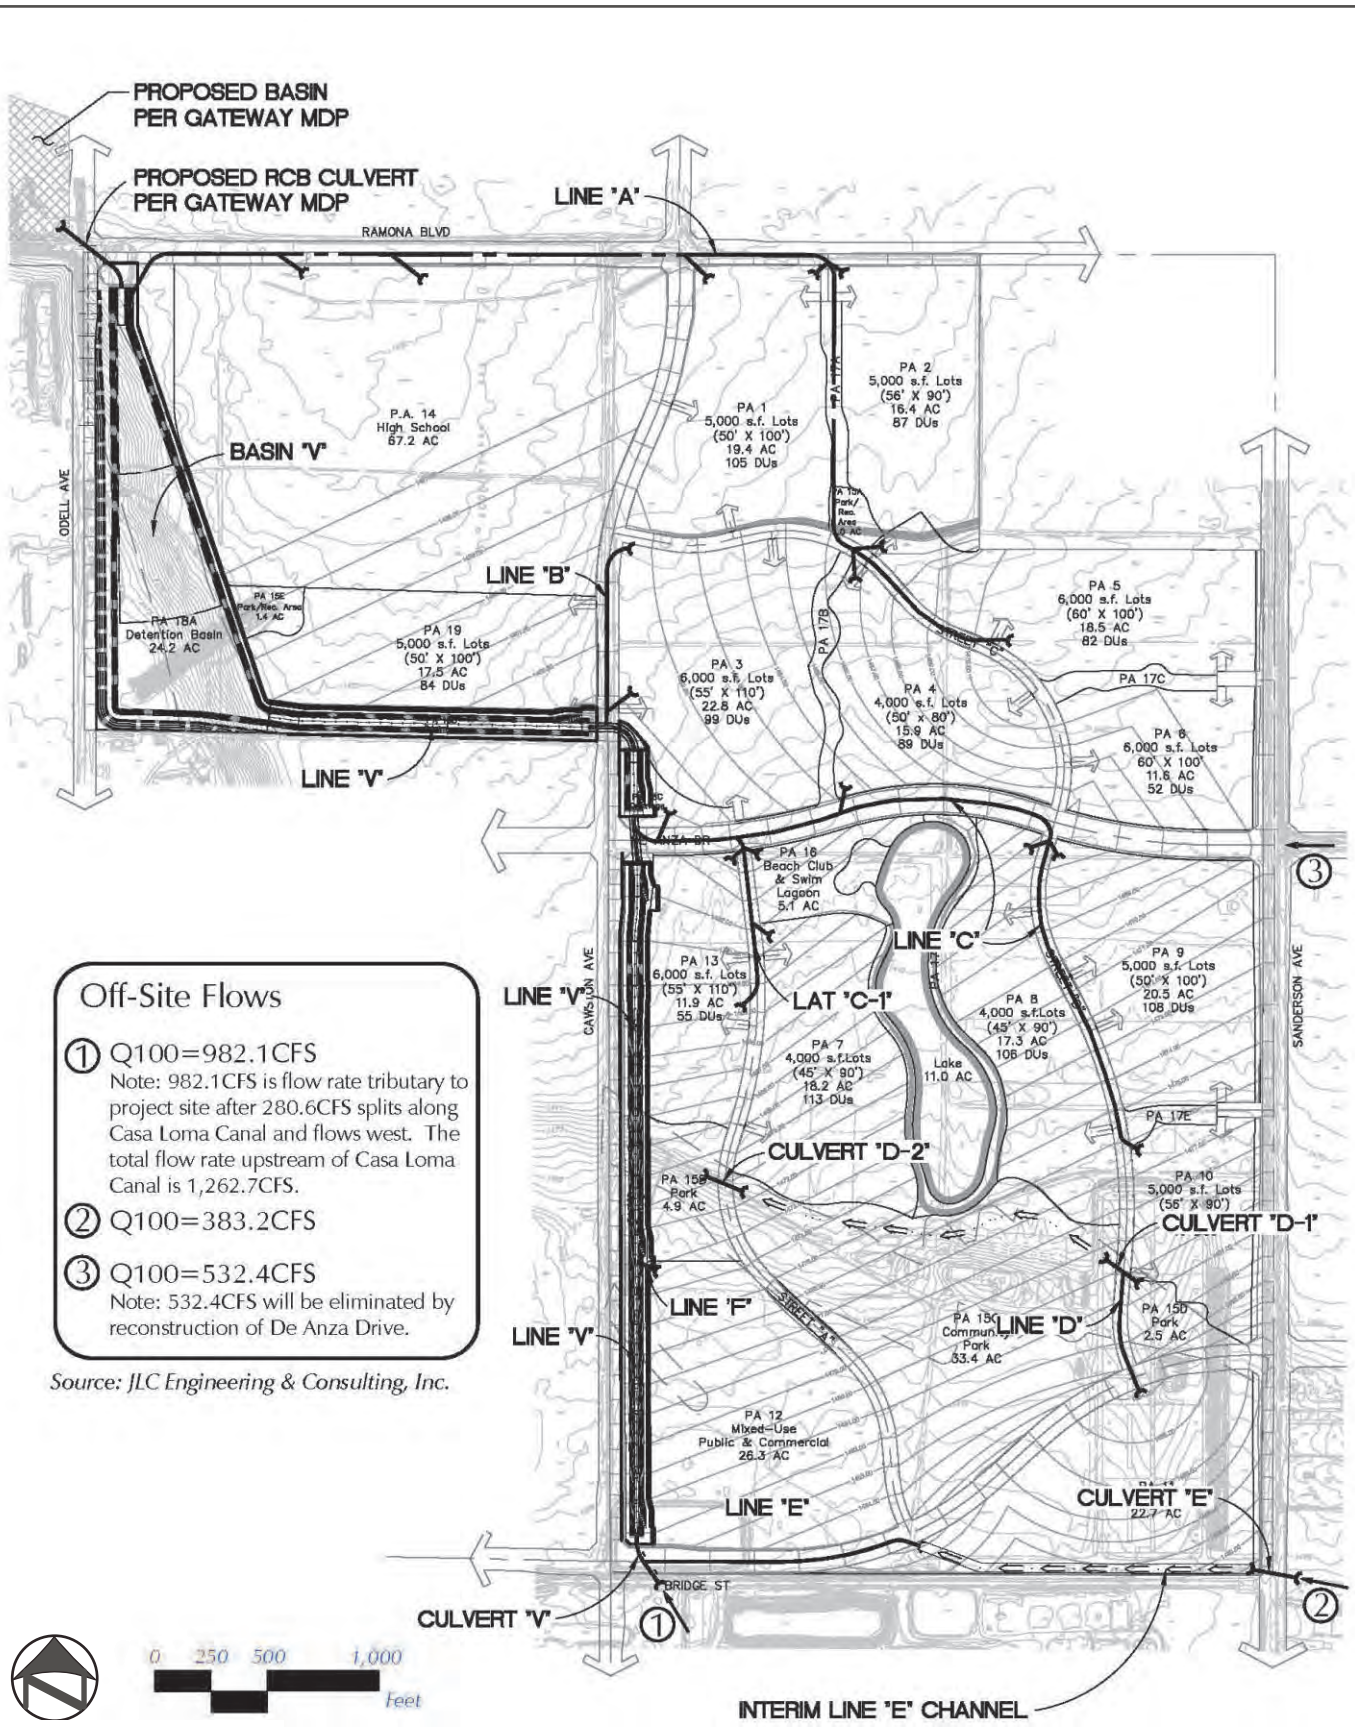
Would the project substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, in a manner that would result in substantial erosion or siltation on- or off-site?

A Drainage Plan has been incorporated into the Specific Plan for the project and is based on the findings in the February 2009 JLC Engineering Hydrology Study referenced above. Proposed drainage facilities are shown on *Figure 5.8-2, On-Site Drainage Plan*. The project site generally drains in a northwesterly direction toward the San Jacinto River, primarily in a sheet flow pattern. The northerly portion of the project site is within the 100-year floodplain. The Drainage Plan provides 100-year flood protection for the project site for the interim and ultimate conditions as described below.

Interim Condition

The interim condition assumes that the off-site area is undeveloped in the existing condition, and the on-site development of the Villages of San Jacinto and corresponding infrastructure is functional. These interim drainage facilities would be developed concurrently with phase I, and are required to control and convey the interim flow rates originating from the off-site area. Interim condition calculations were used to determine the points where flows enter the site and to size the corresponding facilities. Following is a summary of the interim drainage facilities:

- Culvert V, shown on *Figure 5.8-2*, is a proposed culvert south of the Bridge Street and Cawston Avenue intersection that will collect the runoff that overtops the Casa Loma Canal Siphon. The proposed culvert will discharge the runoff into the Line V Channel. The culvert will provide 100-year flood protection for Bridge Street. The ultimate flow rate will substantially decrease once the San Jacinto Master Drainage Plan (MDP) facilities Line D and Casa Loma Basin are constructed.
- Culvert E shown on *Figure 5.8-2* is a proposed culvert located north of the intersection of Sanderson Avenue and the Casa Loma Canal. Based on the current topography, the runoff emanating from the east side of Sanderson Avenue will overtop Sanderson Avenue and enter the project site. As a result, a culvert and earthen channel system have been proposed at the southeast corner of PA 11. These facilities will convey the 100-year flow rate to the Line E system. The San Jacinto MDP proposes drainage system Line E2 will ultimately collect the flows emanating east of Sanderson Avenue.
- The earthen roadway on the land east of Sanderson Avenue, north and south of the intersection of DeAnza Drive and Sanderson Avenue, is not a permitted structure and diverts substantial runoff to the project site, indicated as Off-site Flow 3 on *Figure 5.8-2*.



This diversion occurs because the height of the earthen roadway produces a ponding condition south of the earthen roadway, which forces flows to overtop Sanderson Avenue. The roadway will be reconstructed and lowered to an elevation that will eliminate the ponding condition and allow flows to overtop this roadway, thereby eliminating the overtopping condition on Sanderson Avenue.

Ultimate Condition

The ultimate condition assumes that the San Jacinto MDP systems are in place and functional. With these facilities in place, the off-site area that is tributary to the Villages of San Jacinto is reduced to the area between the Casa Loma Canal and Bridge Street.

Figure 5.8-2 provides the locations where the existing off-site runoff enters the project site (1, 2, and 3) and the corresponding 100-year peak flow rate for the interim condition. However, the runoff entering the project site will eventually be eliminated with the implementation of the San Jacinto MDP.

The implementation of the San Jacinto MDP is based on the timing of the development of the surrounding area. As a result, the construction timeline for the proposed San Jacinto MDP drainage facilities is unknown. Consequently, the project incorporates a drainage plan that will not impact upstream and downstream property owners but will provide flood protection for the overall project site. The drainage plan will incorporate a vegetative channel and a detention/water quality basin, which are designated as Line V and Detention Basin V. These two facilities are the major backbone infrastructure that will collect the runoff that emanates from off-site and on-site areas. Line V and Detention Basin V have been designed to convey and control the interim flow rate and ultimate flow rate. As discussed previously, the interim flow rate results in a runoff rate that exceeds the ultimate condition flow rate. The Line V Channel will allow for the connection of several storm drain laterals. The limits of the storm drain laterals are based on the street design policy implemented by the City of San Jacinto and the County of Riverside. These storm drain laterals will provide 100-year flood protection for the on-site planning areas and ensure that downstream properties would not be impacted by increased flows released from the project site.

Villages of San Jacinto EIR

On-Site Drainage Plan

FIGURE 5.8-2

INTENTIONALLY LEFT BLANK

Because the San Jacinto MDP facilities would be designed to handle the increase in drainage from the project site once developed, impacts to surface water would not be significant. However, in accordance with San Jacinto requirements, the project shall be required to participate in the San Jacinto River levee financing project (see *Section 5.8.5, Mitigation Measures*, Mitigation Measure 5.8-a).

Would the project create or contribute runoff water that would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources or polluted runoff?

As discussed above, the project incorporates a drainage plan that will not impact upstream and downstream property owners but will provide flood protection for the overall project site. Implementation of the San Jacinto MDP is based on the timing of the development of the surrounding area and will further improve drainage systems in the project area.

Would the project place housing within a 100-year flood hazard area as mapped on a federal Flood Hazard Boundary or Flood Insurance Rate Map or other flood hazard delineation map?

The northern portion of the project site is located within Zone A (100-year floodplain as mapped by FEMA) of the San Jacinto River. Development within the floodplain may result in an impedence to flow and an increase in the base flood elevation. Because a portion of the proposed development is proposed to be constructed within the limits of the 100-year floodplain, development of the proposed project will result in potentially significant impacts relating to flood hazards. As discussed above, the project drainage plan will provide 100-year flood protection for the project site and will not adversely affect downstream properties. However, mitigation is required to have the project removed from the appropriate FEMA floodplain map. In order to avoid impacts, mitigation is provided (see *Section 5.8.5, Mitigation Measures*, Mitigation Measure 5.8-c).

It should be noted that the project site elevation will be raised during grading activities to ensure that future structures are outside of the 100-year floodplain.

Would the project place within a 100-year flood hazard area structures which would impede or redirect flows?

As discussed in preceding responses, the project drainage plan will ensure that adequate flood protection is provided and the placement of new structures would not impede or redirect 100-year flows or result in on-site or off-site flooding as a result of project implementation.

Would the project expose people or structures to a significant risk of loss, injury, or death involving flooding, including flooding as a result of the failure of a levee or dam?

The project would not expose people or structures to a significant flood risk as discussed in the preceding responses. Adequate flood protection will be provided in the absence of the planned San Jacinto River levee project, which will provide additional protection from flooding in the project area.

Would the project otherwise substantially degrade water quality?

The project would not have a significant impact on water quality as discussed in detail in the first impact response above.

5.8.5 Mitigation Measures

5.8-a The project is located within the San Jacinto – Area Drainage Plan (SJ-ADP), which is a financing mechanism used to offset costs for construction of proposed Master Drainage Plan (MDP) facilities. The project will be charged a per-acre fee in order to pay a fair share of the price of area-wide drainage facilities.

5.8-b If dewatering becomes necessary during construction, all discharges shall be in accordance with Santa Ana Regional Water Quality Control Board requirements which mandate that dewatered groundwater be tanked and hauled to a legal disposal site for treatment. Dewatering shall not occur in on-site drainages or water features. In addition, if dewatering becomes necessary during construction, a National Pollution Discharge Elimination System dewatering permit shall be obtained from the Santa Ana Regional Water Quality Control Board.

5.8-c All buildings shall be located outside of the 100-year floodplain. The applicant shall process a Flood Insurance Rate Map (FIRM) map revision. Further, the applicant shall obtain a Conditional Letter of Map Revision (CLOMR) prior to issuance of building permits. The project applicant, or subsequent property owners, shall obtain flood insurance, to the extent required by law, to protect against any damage that might occur during a flood event. It must be noted that at the time of EIR publication, the applicant and City had initiated the CLOMR process with the Riverside County Flood Control and Water Conservation District.

5.8-d During construction, the project will incorporate all City of San Jacinto construction Best Management Practices (BMPs). These BMPs include the following:

- Erosion control BMPs, including temporary seeding and permanent seeding
- Soil stabilization BMPs
- Sediment control BMPs, including silt fence perimeter controls, surface roughening, tree or natural vegetation preservation and protection, temporary gravel construction entrance/exit, temporary diversions, permanent diversions, outlet stabilization, inlet protection, temporary sediment basins, and gravel bay barriers.
- Wind erosion BMPs
- Minimize contact with stormwater BMPs, including BMPs for construction vehicles and equipment maintenance, fueling, and washing; materials maintenance; and construction material loading, unloading, and access area controls.
- Non-stormwater BMPs.

5.8-e The project applicant will need to develop a Stormwater Pollution Prevention Plan (SWPPP) pursuant to NPDES Stormwater Discharge Associated with Construction Activity Guidelines (Water Quality Order 99-08-DWQ). The SWPPP will identify all BMPs that will prevent construction pollutants from contacting stormwater. Measures shall also be designed so as to prevent all products of erosion from moving off site into receiving waters. Provisions will also be included to ensure that BMPs are monitored and success recorded.

5.8-f Structural BMPs are required for new development to improve water quality of stormwater runoff. In order to meet NPDES regulations, the design volume or design flow to be treated must reduce pollutants to the Maximum Extent Practicable (MEP). This project will incorporate a water quality extended detention basin to provide water quality treatment for the runoff emanating from the project site, a volume-based BMP, and a flow-based BMP. Once the project is complete, maintenance will be the responsibility of the Villages of San Jacinto homeowners association.

In addition to sizing techniques, several quantity-control BMPs shall be implemented to control runoff:

- Rainfall shutoff devices shall be used to prevent irrigation during and after precipitation
- Irrigation systems shall utilize a dripping system to eliminate nuisance runoff
- Backflow preventer/pressure regulators shall be installed.

The project applicant will need to develop a Water Quality Management Plan pursuant to NPDES Permit No. CAS 618033, order No. R8-2002-001. The Water Quality Management Plan will identify all final site BMP requirements.

The following BMPs may be incorporated into final site designs:

- Construct community streets, sidewalks, and parking lot aisles to the minimum widths necessary
- Incorporate landscape treatment for parking lot runoff
- Use unit pavers or other equivalent porous material to construct walkways, alleys, and other low-traffic areas
- Utilize trees in landscaping plans to maximize canopy interception and water conservation
- Plant native trees and maximize canopy interception and water conservation
- Drain rooftops into adjacent landscaping prior to discharging to the storm drain
- Vegetate slopes with native or drought tolerant vegetation
- Install energy dissipaters at the outlets of new storm drains that enter the regional storm drain system that eventually feeds into the San Jacinto River.
- Utilize and install "high to medium efficiency" Post Construction BMP filtration system within the proposed water quality basin that would help reduce as many bacteria and viruses as possible from entering the downstream local stormwater collection system. This system must follow the specifications of the California Stormwater Handbook to ensure that the system provides maximum bacteria/viral capture.

5.8.6 Residual Impacts/Level of Significance after Mitigation

After application of the proposed mitigation measures, any potentially significant impacts relating to hydrology, groundwater, or water quality that are attributable to the development and operation of the proposed project would be reduced to a level below significant. Therefore, no significant unavoidable impacts are expected.

5.9 TRANSPORTATION, CIRCULATION, AND ACCESS

5.9.1 Introduction and Methodology

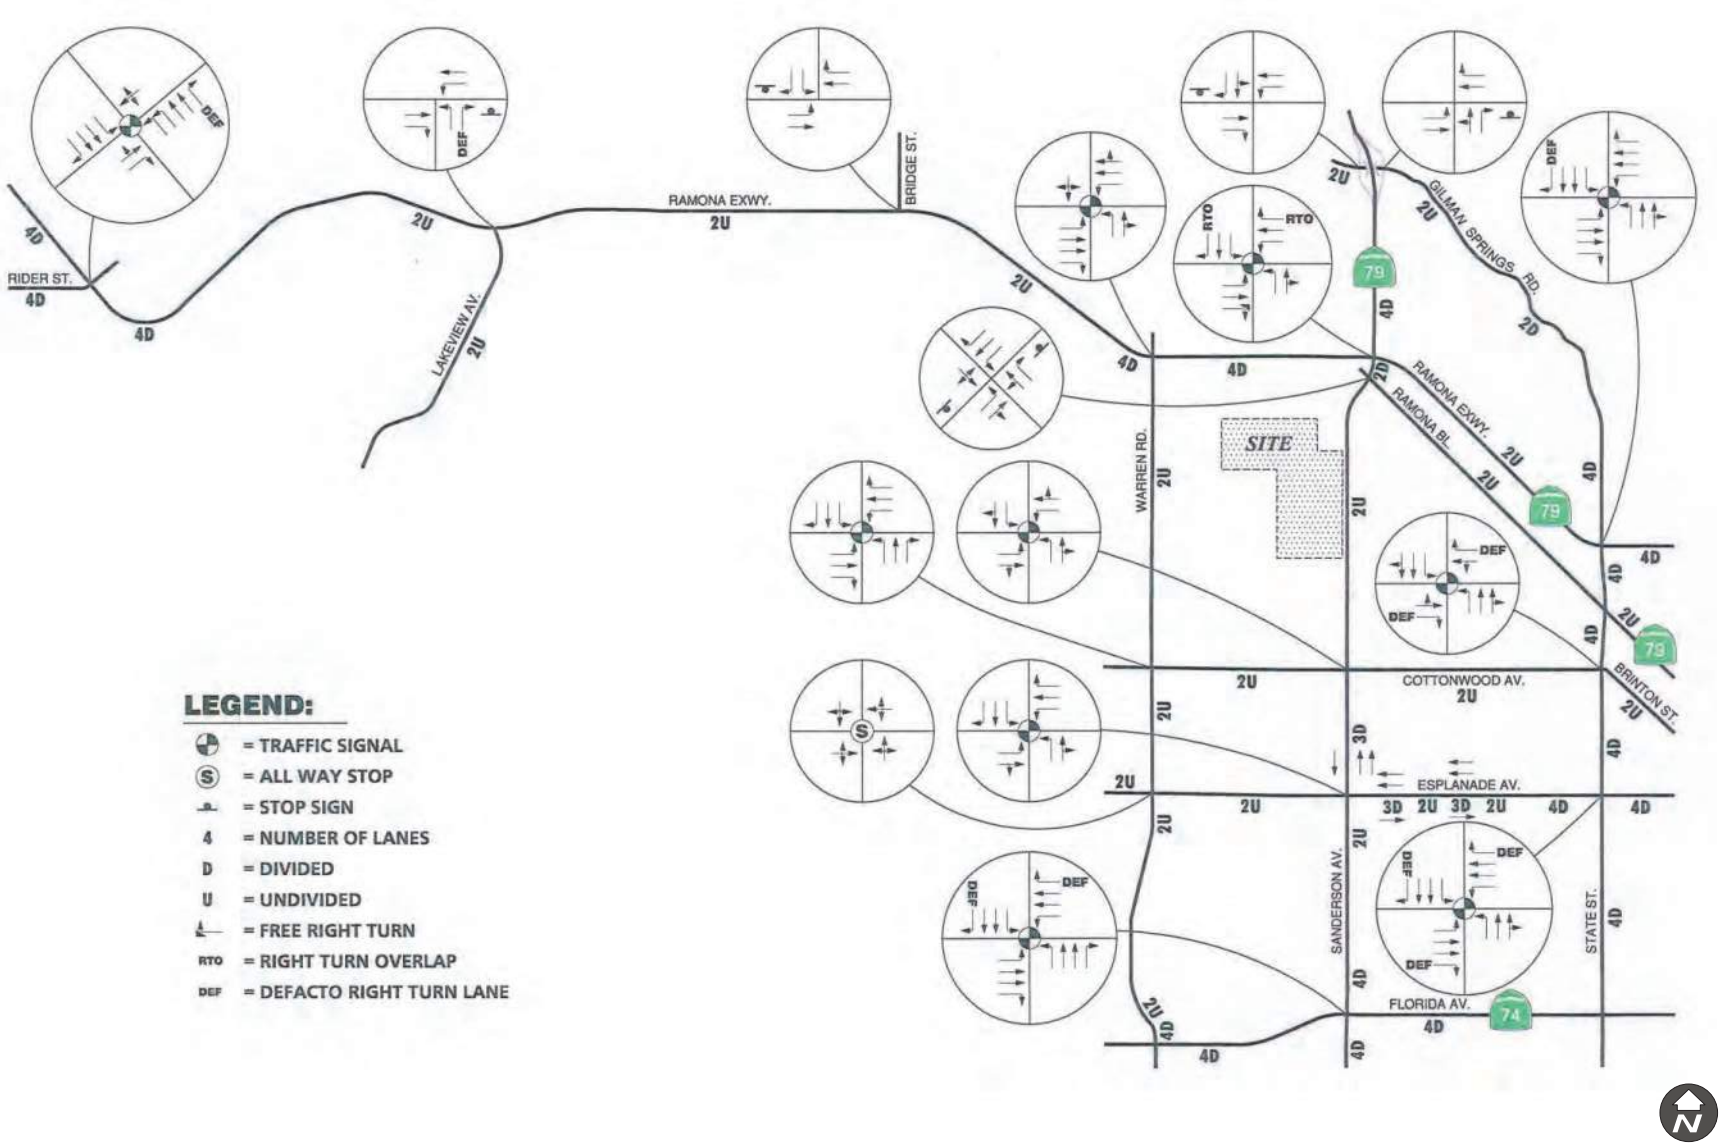
The following analysis of potential traffic, circulation and access impacts associated with project implementation is based on *the Villages of San Jacinto Traffic Impact Analysis* prepared by Urban Crossroads, April 24, 2009, included in *Appendix H* of this report. This latest report is an update of the May 23, 2005, Traffic Impact Analysis prepared by Urban Crossroads for the April 2006 DEIR. The original report was revised to reflect changes in project land uses, revised phasing plan, and revisions to the Mid-County Parkway southerly alignment within the project study area.

The traffic study analyzes the potential impacts of cumulative conditions representing the phased occupancy timing of the project, including Phase I, year 2015; Phase II, Year 2017; Phase III, Year 2023; and General Plan build-out conditions in Year 2035. The traffic impact analysis documents existing traffic conditions in the vicinity of the project site, Existing Plus Ambient Plus Project conditions for Phase I, Phase II and Phase III conditions; Existing Plus Ambient Plus Cumulative conditions (EAC 2015); Existing Plus Ambient Plus Cumulative plus Phase I conditions (EACP 2015); Existing Plus Ambient Plus Cumulative conditions (EAC 2017); Existing Plus Ambient Plus Cumulative Plus Phase I and Phase II conditions (EACP 2017); Existing Plus Ambient Plus Cumulative conditions (EAC 2023); Existing Plus Ambient Plus Cumulative Plus Phases I through III conditions (EACP 2023); evaluation of General Plan build-out (2035) with project conditions; and identifies on-site and off-site improvements and system management actions to achieve adequate level of service requirements as required by the City of San Jacinto.

The traffic analysis utilizes information obtained from City of San Jacinto staff to define the study area intersections and identify other development and area-wide growth calculations used in traffic counts. Due to the project's size and phased implementation plan, the traffic analysis was reflective of the phasing plan. Because the mitigation measures will be implemented as the project is constructed and traffic improvements become necessary, the phasing plan is reflected in the on-site mitigation measures. The City of San Jacinto and Riverside County General Plan Circulation Elements were used to identify the regional and City street network and roadway cross-sections in the study area. The traffic study has been prepared in conformance with the goals and requirements of the San Jacinto General Plan Circulation Element. Traffic operations and level of service conditions were evaluated pursuant to the 2000 Highway Capacity Manual (HCM).

As indicated in *Section 3.0, Project Description,* the proposed project would result in 1,016 low to medium density single-family dwelling units, a 2,000 student-high school, 247,000 square feet

of neighborhood retail commercial uses, 343,000 square feet of mixed-use development and approximately 43 acres of park land. However, in the event that the high school is not built, an additional 313 single-family housing units would be constructed, which would result in the potential for 1,329 units to be developed on site. While on the surface it may seem that the 1,329 unit count scenario would result in more traffic, traffic analyses are based on peak hour measurements, which for this project, would be more trip-intensive in the school scenario. Therefore, this traffic analysis reflects the 1,016 unit project with high school scenario, in order to provide the public with a "worst case scenario."



5.9.2 Existing Conditions

The project site is generally located south of Ramona Expressway and directly west of North Sanderson Avenue in the City of San Jacinto. North Sanderson Avenue is identified as an urban arterial roadway in the City of San Jacinto General Plan Circulation Element. *Figure 5.9-1, Existing Lane and Intersection Conditions*, illustrates the primary roadway components of the study area street network and identifies the number of traffic lanes for each roadway and existing intersection traffic controls.

Intersection Conditions

Traffic flow on arterial streets is most constrained at intersections; therefore, the traffic analysis focuses on the operating conditions of critical intersections during peak travel periods. The traffic report utilized information obtained from City of San Jacinto Transportation staff to identify the key intersections within the study area for analysis. The following intersections were analyzed in this study:

- Rider Street (NS) at:
  - Ramona Expressway (EW)
- Lakeview Avenue (NS) at:
  - Ramona Expressway (EW)
- Bridge Street (NS) at:
  - Ramona Expressway (EW)
- Warren Road (NS) at:
  - Ramona Expressway (EW)
  - Cottonwood Avenue (EW)
  - Esplanade Avenue (EW)

SOURCE: URBAN CROSSROADS, MARCH 2009

Existing Lane and Intersection Conditions

FIGURE 5.9-1

INTENTIONALLY LEFT BLANK

- Sanderson Avenue (NS) at:
  - Gilman Springs Road SB Ramps (EW)
  - Gilman Springs Road NB Ramps (EW)
  - Ramona Expressway (EW)
  - Ramona Boulevard North (EW)
  - Cottonwood Avenue (EW)
  - Esplanade Avenue (EW)
  - Florida Avenue (SR-74) (EW)
- State Street (NS) at:
  - Ramona Expressway (EW)
  - Cottonwood Avenue (EW)
  - Esplanade Avenue (EW).

The existing conditions of each intersection listed above are characterized by Average Daily Trip (ADT) volumes and Level of Service (LOS) ratings. *Figure 5.9-2, Existing Traffic Volumes*, illustrates existing ADT volumes on arterial streets in the study area. *Figure 5.9-3, Existing AM Peak Hour Intersection Volumes*, and *Figure 5.9-4, Existing PM Peak Hour Intersection Volumes*, depict the distribution of existing ADT volumes on the study area roadway system. Existing ADT volumes are based on direct machine counts or factored from peak hour counts conducted for Urban Crossroads, Inc. in conjunction with the project traffic study.

In evaluating the existing intersection conditions, a "Level of Service (LOS)" rating, which consists of A through F, is used. LOS A indicates excellent conditions of uninterrupted free-flow traffic operations and LOS F indicates poor conditions of interrupted flow and congested operations (gridlock). Complete definitions of LOS categories are included in the Traffic Impact Analysis, included in *Appendix H* to this EIR. Different factors are considered in determining LOS for each intersection and are dependent on the type of intersection control used (i.e., signal, street stop, etc.). For signalized intersections, average total delay per vehicle for the overall intersection is used to determine level of service. For stop sign–controlled intersections, the calculation of LOS is dependent on the occurrence of gaps occurring in the traffic flow of the main street. For all way stop controlled intersections, the LOS criteria for this type of intersection analysis are also based on average total delay per vehicle for the overall intersection. The traffic analysis considers LOS D to be the minimum acceptable operating condition for intersections consistent with the adopted standards of the City of San Jacinto.

For the project area, traffic demands are highest at key intersections during the A.M. and P.M. peak hour periods. *Table 5.9-1, Existing Intersection Conditions* summarizes the results of evaluating existing peak hour traffic operations for intersections in the study area, and includes information relative to each intersection's geometrics, traffic control device and existing LOS.

INTENTIONALLY LEFT BLANK

The data presented in *Table 5.9-1, Existing Intersection Conditions* indicates that the following intersections are currently operating at an unacceptable LOS (LOS E or lower):

- Lakeview Avenue (NS) at:
  - Ramona Expressway (EW)
- Sanderson Avenue (SR-79 SB Ramps) (NS) at:
  - Gilman Springs Road SB (EW)
- Sanderson Avenue (NS) at:
  - Ramona Expressway (EW)
  - Ramona Boulevard (EW).

The above outlined existing traffic conditions warrant traffic signals at the following study area intersections:

- Lakeview Avenue (NS) at:
  - Ramona Expressway (EW)
- Warren Road (NS) at:
  - Esplanade Avenue (EW)
- Sanderson Avenue (SR-79 SB Ramps) (NS) at:
  - Gilman Springs Road (EW)
- Sanderson Avenue (SR-79 NB Ramps) (NS) at:
  - Gilman Springs Road (EW).

Alternative Transportation

Public bus service in the project vicinity is provided by the Riverside Transit Agency. Three bus routes operate within the City of San Jacinto. However, there are currently no transit facilities or designated bikeways operating in the study area.

Regulatory Framework

The Western Riverside Council of Governments (WRCOG) is a council which is comprised of members representing 15 local jurisdictions in western Riverside County, including the City of San Jacinto. The WRCOG functions to facilitate collective assessment of regional issues, such as traffic, by the various representative jurisdictions. In June 2004 WRCOG adopted the

Transportation Uniform Mitigation Fee (TUMF) 10-Year Strategic Plan and Transportation Improvement Program Development Guidelines.

The purpose of the TUMF program is to establish a comprehensive funding source for infrastructure improvements to mitigate cumulative regional transportation impacts of new development on regional arterial highways (Parsons Brinckerhoff Quade & Douglas, Inc., June 2004). The TUMF program has 5 primary goals that are articulated as a basis for developing specific project priorities and selection criteria. These goals are summarized as follows:

- ***Sustain Mobility*** – Mitigate the transportation system impacts of new development
- ***System Continuity*** – Enhance the continuity of the regional arterial highway system
- ***Project Development*** – Encourage systematic project development and provide flexibility to advance TUMF projects promptly through completion
- ***Leverage Funds*** – Secure additional matching funds for TUMF system improvements
- ***Regional Benefit*** – Ensure TUMF program revenues are distributed to maximize mitigation of new development impacts.

The TUMF program is intended to address cumulative traffic impacts of new development to the region and therefore TUMF program funded improvements are focused primarily on regional arterial highways. New development in Western Riverside County places additional demand on the regional transportation system to provide safe and convenient access for new residents and employees. The additional demand on the transportation facilities reduces mobility absent adequately and timely funded infrastructure improvements implemented to meet growing demands. As such, WRCOG has developed and implemented the TUMF program which requires new development to contribute revenues to partially fund improvements that will mitigate the transportation impacts of new developments. TUMF investments are then focused on those regional facilities most impacted by new development. The TUMF program assigns impact fees on a per dwelling unit basis for residential development and a per square foot basis for non-residential uses (i.e., commercial, industrial, office).

The City of San Jacinto also implements a Development Impact Fee (DIF) which consists of a "Streets and Roads" component and a "Traffic Signals" Component. The DIF program assigns impact fees on a "per acre" basis for non-residential development and a per unit basis for residential development. Fee calculations for both the TUMF and DIF programs are shown in *Section 5.9.5*.

5.9.3 Significance Criteria

Based on the criteria identified in Appendix G of the CEQA Guidelines, the proposed project would have a significant impact on transportation, circulation and access if it:

1. Would cause an increase in traffic that is substantial in relation to the existing traffic load and capacity of the street system (i.e., result in a substantial increase in either the number of vehicle trips, the volume to capacity ratio on roads, or congestion at intersections)
2. Would exceed, either individually or cumulatively, a level of service standard established by the County Congestion Management Agency for designated roads or highways
3. Would result in a change in air traffic patterns, including either an increase in traffic levels or a change in location that results in substantial safety risks
4. Would substantially increase hazards due to a design feature (e.g., sharp curves or dangerous intersections) or incompatible uses (e.g., farm equipment)
5. Would result in inadequate emergency access
6. Would result in inadequate parking capacity
7. Would conflict with adopted policies, plans, or programs supporting alternative transportation (e.g., bus turnouts, bicycle racks).

5.9.4 Impacts

Would the project cause an increase in traffic that is substantial in relation to the existing traffic load and capacity of the street system (i.e., result in a substantial increase in either the number of vehicle trips, the volume to capacity ratio on roads, or congestion at intersections)?

Would the project exceed, either individually or cumulatively, a level of service standard established by the County Congestion Management Agency for designated roads or highways?

Project Traffic

In order to characterize potential traffic impacts associated with the project, a characterization of the project's contribution to local traffic levels must occur. Site traffic is characterized by trip generation, trip distribution, modal split, and trip assignment.

As indicated in *Section 5.9.1*, the proposed project's "worst case" traffic impact scenario would be a land use scenario that includes construction of the planned high school, in effect a 1,016-unit development. Trip generation rates are based upon the proposed land use plan and data collected by the Institute of Traffic Engineers (ITE), *Trip Generation Manual, 7th Edition*. Trip generation rates for each proposed land use are shown in *Table 5.9-2, Project Trip*

Generation Rates, while daily and peak hour traffic generated by the proposed project is shown in *Table 5.9-3, Trip Generation Summary*.

TSF = Thousand Square Feet

[2] Internal Capture is the reduction of the overall traffic due to the compatability of land uses (proposed residential, high school, park, office, and shopping center) within the project site.

[3] "Pass-By" reduction rates have been used to account for traffic that will access the site as an intermediate stop on the way to a primary destination.

Due to the size and diversity of land uses of the proposed project a certain portion of the anticipated ADT will simply circulate internally rather than exit the development to travel to other destinations. This factor, deemed "internal capture," would include vehicle trips from the residential areas to school, residential areas to shopping center and residential areas to the mixed-use area. The number of internal capture trips was calculated for each building phase of the project. As shown in *Table 5.9-3*, the project is estimated to generate a total of 27,166 net external ADT for all four phases after accounting for internal trips and "pass-by" trips (i.e., traffic that will access the site on the way to another primary destination).

Trip distribution represents the directional orientation of traffic to and from the project site. Trip distribution is heavily influenced by the geographical location of the site, the location of employment, commercial and recreational opportunities and the proximity to the regional freeway system. Trip distribution for this project is based upon near-term conditions which include those roadway facilities which are either in place or are expected to be in place over the next several years. Roadway construction and improvements that are assumed to be in place in conjunction with each phase of the project are detailed in Section 4.2 of the Traffic Impact Analysis in *Appendix H.*

Due to the lack of anticipated public transit facilities within this portion of the City of San Jacinto, the traffic-reducing impact of public transportation facilities has not been considered for this project. Should transit facilities become a part of this area, they would in effect reduce traffic levels and reduce anticipated impacts described herein.

The assignment of traffic from the site to the adjoining roadway system has been based upon the site's trip generation, trip distribution, proposed arterial highway system and local street systems. Project generated traffic is then combined with background traffic and projected future traffic to estimate impacts on the study area roadways as described below.

Cumulative Traffic

In order to fully address traffic impacts, an impact analysis assuming the ultimate build out of other planned projects (cumulative projects), must be performed. These projects were based on information provided by the City of San Jacinto and County of Riverside and include projects that are under construction or are under review in the project area.

Several cumulative projects were identified for this analysis and have been divided into 28 traffic analysis zones (TAZ). *Table 5.9-4, 2023 Cumulative Project Trip Generation*, provides a summary of the total anticipated units (if residential) or square footage (if commercial) and daily AM and PM peak hour trips assumed in each TAZ based on known project information. Daily and peak hour trips that would be generated by the additional development proposals in the study area were calculated and the projected generated traffic was distributed and assigned to the study area street system.

[1] DU = Dwelling Units
TSF = Thousand Square Feet
STU = Students
AC = Acres

[2] SFDR = Single-Family Detached Residential

[3] Internal Capture is the reduction of the overall traffic due to the compatability of land uses (proposed residential), elementary within a cumulative project site.

[4] "Pass-By" reduction rates have been used to account for traffic that will access the site as an intermediate stop on the way to a primary destination.

In addition to project-generated traffic and anticipated traffic generation from additional approved or pending development in the study area, area wide growth (ambient growth) has been considered in the traffic analysis. Based on information obtained by City staff, future traffic volumes have been calculated by using an anticipated 3% annual growth rate for the years 2008–2015 and a 1% growth rate for the years 2015–2023, which has been added to project-related and other development-related daily and peak hour traffic volumes (see Exhibit 4-K through 4-T in *Appendix H* for graphical depictions of each cumulative project's location and anticipated trip distribution).

Intersection Impacts for Existing Plus Ambient Plus Project Conditions

In order to identify direct project impacts, interim year analyses were performed for three Existing Plus Ambient Plus Project (EAP) scenarios. These scenarios don't include the cumulative projects that were identified above, but do include ambient traffic growth rates for each study year which corresponds to the project phasing. The following three sets of traffic volume conditions have been forecasted:

- 2015 EAP with Project Phase I
- 2017 EAP with Project Phases I + II
- 2023 EAP with Project Phases I + II + III.

The intersection levels of service for each of the scenarios are shown in *Table 5.9-5* through *Table 5.9-7*. Those intersections shown as "Does Not Exist" would not have been built at the timing for the scenario being analyzed. The intersection turning movement volumes for each scenario are shown on Exhibits 5-A through 5-F in *Appendix H*.

[1] When a right turn is designated, the lane can either be striped or unstriped. To function as a right turn lane there must be sufficient width for right turning vehicles to travel outside the through lanes.

L = Left; T = Through; R = Right; 1! = Left-Thru-Right Lane; 1> = Right Turn Overlap; 1>> = Free-Right Turn Lane; **1** = IMPROVEMENT

[2] Delay and level of service calculated using the following analysis software: Traffix, Version 7.9 R4 (2008). Per the 2000 Highway Capacity Manual, overall average intersection delay and level of service are shown for intersections with traffic signal or all way stop control. For intersections with cross street stop control, the delay and level of service for worst individual movement (or movements sharing a single lane) are shown.

[3] TS = Traffic Signal
CSS = Cross Street Stop
AWS = All Way Stop

* Those intersections shown as "Does Not Exist" would not have been built at the timing for the scenario being analyzed.

As shown in *Table 5.9-5*, the following intersections are projected to operate at unacceptable LOS (i.e., LOS E or worse) during peak hours without improvements for the 2015 EAP, Phase I scenario:

- Bridge Street (NS) at:
  - Ramona Expressway (EW)
- Warren Road (NS) at:
  - Esplanade Avenue (EW)
- Sanderson Avenue (SR-79 NB Ramps) (NS) at:
  - Gilman Springs Road (EW)
- Sanderson Avenue (NS) at:
  - Ramona Boulevard (EW) Realigned
  - Florida Avenue (SR-74) (EW).

With improvements, all of the study area intersections are projected to operate at acceptable LOS during the peak hours.

[1] When a right turn is designated, the lane can either be striped or unstriped. To function as a right turn lane there must be sufficient width for right turning vehicles to travel outside the through lanes.

L = Left; T = Through; R = Right; 1! = Left-Thru-Right Lane; 1> = Right Turn Overlap; 1>> = Free-Right Turn Lane; **1** = IMPROVEMENT

[2] Delay and level of service calculated using the following analysis software: Traffix, Version 7.9 R4 (2008). Per the 2000 Highway Capacity Manual, overall average intersection delay and level of service are shown for intersections with traffic signal or all way stop control. For intersections with cross street stop control, the delay and level of service for worst individual movement (or movements sharing a single lane) are shown.

[3] TS = Traffic Signal
CSS = Cross Street Stop
AWS = All Way Stop
Italicized = Lane to be constructed only with the +313 DU Project Alternative

Intersection Analysis for Cumulative Conditions with Project

In order to identify the improvements required to achieve acceptable levels of service for each Interim Year with cumulative development (as described in *Table 5.9-4*) with project conditions, the following EACP (existing + ambient + cumulative + project) traffic forecast scenarios have been provided:

- 2015 EACP with Project Phase I
- 2023EACP with Project Phases I + II
- 2023 EACP with Project Phases I + II + III.

For EACP 2015 traffic conditions, all of the study area intersections are projected to operate at unacceptable LOS E or F during the peak hours without improvements. As shown in *Table 5.9-9*, some of the improvements required to achieve acceptable LOS exceed the General Plan typical roadway cross sections and are therefore not feasible due to the uncertainty of obtaining adequate right-of-way for such measures. These instances include the triple left turn lanes required at Warren Road at Ramona Expressway, the extensive improvements required along Sanderson Avenue (which don't provide acceptable LOS for the PM peak hour), and the three through lanes along Esplanade Avenue. The improvements which go beyond General Plan standards are due to the lack of alternative routes which would be provided upon completion of the Mid-County Parkway and SR-79 improvements which are not included in the EACP 2015 analysis. In order to minimize required improvements, a further analysis was done which includes completion of the Mid-County Parkway and SR-79 improvements for those intersections affected by these projects. The analysis also included required improvements for General Plan build-out conditions. As shown on *Table 5.9-10*, the improvements in excess of the ultimate planned roadway cross-sections at the study intersections would not be required to achieve acceptable LOS for the EACP 2015 scenario (with completion of the Mid-County Parkway and SR-79 improvements). Further, insuring that adequate right-of-way exists would entail an amendment to the Circulation Element. Because such an amendment can't be accommodated for only a portion of the City, it would result in a Circulation Element amendment that is City-wide which is not appropriate. However, it should be noted that completion of these regional improvements can't be guaranteed by the City. As such, the project would contribute to a significant unmitigable impact for EACP 2015 traffic conditions if these improvements are not in place.

[3] TS = Traffic Signal

As shown on *Table 5.9-11*, for 2017 EACP conditions all of the study intersections are projected to operate at unacceptable LOS E or F during the peak hours without improvements. As in the 2015 EACP scenario, some required improvements would exceed the General Plan typical roadway cross sections and are therefore not feasible due to the uncertainty of obtaining adequate right-of-way for such measures. As shown on *Table 5.9-12*, the improvements in excess of the ultimate planned roadway cross-sections at the study intersections would not be required to achieve acceptable LOS for the EACP 2015 scenario with completion of the Mid-County Parkway and SR-79 improvements. However, it should be noted that completion of these regional improvements can't be guaranteed by the City. As such, the project would contribute to a significant unmitigable impact for EACP 2017 traffic conditions if these improvements are not in place.

L = Left; T = Through; R = Right; 1l = Left-Thru-Right Lane; 1> = Right Turn Overlap; 1>> = Free-Right Turn Lane; 1 = IMPROVEMENT

[2] Delay and level of service calculated using the following analysis software: Traffix, Version 7.9 R4 (2008). Per the 2000 Highway Capacity Manual, overall average intersection delay and level of service are shown for intersections with traffic signal or all way stop control. For intersections with cross street stop control, the delay and level of service for worst individual movement (or movements sharing a single lane) are shown.

[3] TS = Traffic Signal

As shown in *Table 5.9-12*, for 2023 EACP conditions all of the study intersections are projected to operate at unacceptable LOS E or F during the peak hours without improvements. As in the 2017 EACP scenario, some required improvements would exceed the General Plan typical roadway cross sections and are therefore not feasible due to the uncertainty of obtaining adequate right-of-way for such measures. As shown on *Table 5.9-13*, the improvements in excess of the ultimate planned roadway cross-sections at the study intersections would not be required to achieve acceptable LOS for the EACP 2023 scenario with completion of the Mid-County Parkway and SR-79 projects. However, it should be noted that completion of these regional improvements cannot be guaranteed by the City. As such, the project would contribute to a significant unmitigable impact for EACP 2023 traffic conditions if these improvements are not in place.

Intersection Analysis for General Plan Build-Out with Project Phases I + II + III + IV (2035) Conditions

General Plan Build-out with Project Phases I + II + III + IV (2035) Conditions intersection LOS are shown in *Table 5.9-14*. As shown, the following intersections are projected to operate at unacceptable LOS E or F during the peak hours without improvements:

- Warren Road (NS) at:
  - Cottonwood Avenue (EW)
  - Esplanade Avenue (EW)
- Sanderson Avenue (NS) at:
  - Cottonwood Avenue (EW)
  - Esplanade Avenue (EW)

  - Florida Avenue (SR-74) (EW)
- Sanderson Avenue (SR-79 SB Ramps) (NS) at:
  - Gilman Springs Road (EW)
- Sanderson Avenue (SR-79 NB Ramps) (NS) at:
  - Gilman Springs Road (EW)
- State Street (NS) at:
  - Cottonwood Avenue (EW)
  - Ramona Expressway
  - Esplanade Avenue.

As shown in *Table 5.9-14*, for General Plan build-out with project Phases I + II + III + IV (2035) Conditions, study area intersections are projected to operate at LOS D or better with the intersection improvements.

[1] When a right turn is designated, the lane can either be striped or unstriped. To function as a right turn lane there must be sufficient width for right turning vehicles to travel outside the through lanes.

L = Left; T = Through; R = Right; 1! = Left-Thru-Right Lane; 1> = Right Turn Overlap; 1>> = Free-Right Turn Lane; 1 _ = IMPROVEMENT

[2] Delay and level of service calculated using the following analysis software: Traffix, Version 7.9 R4 (2008). Per the 2000 Highway Capacity Manual, overall average intersection delay and level of service are shown for intersections with traffic signal or all way stop control. For intersections with cross street stop control, the delay and level of service for worst individual movement (or movements sharing a single lane) are shown.

[3] TS = Traffic Signal
CSS = Cross Street Stop
AWS = All Way Stop

[4] A traffic signal is not warranted at this location. An alternative to provide acceptable LOS would be to prohibit left turns out.

Construction Related Traffic Impacts

Construction-related traffic would involve approximately 20 to 40 workers per day at the project site during each construction phase. Construction-related traffic would use Sanderson Avenue as the primary north/south access to and from the project site while various east/west routes may be used as appropriate during each phase of the project. Mass grading for the entire site would start in December 2011 and would be completed 7 months after. The grading plans anticipate that cut and fill will be balanced; no export or import of soil is planned. Phase I would be completed in December 2015. Fine grading for Phase II would start immediately after the completion of Phase

I in January 2016. Phase II would be completed in December 2017. Phase III would commence immediately after the completion of Phase II in December 2017. Phase III would include the construction of single-family residences and a high school. In July 2018, six months into the development phase, construction of the high school would start. Phase III, including the high school, would be completed in December 2023. Construction of the remaining nonresidential land uses in Phase IV would start in January 2024 and would be completed by December 2033.

The project would involve multiple construction subphases: 1) mass grading, 2) fine site grading of individual phases, 3) utilities/infrastructure (trenching), 4) building construction, 5) paving, and 6) architectural coating. Phases I, II, III, and IV would involve separate construction subphases with the exception of mass grading, which will cover the entire project site and occur during Phase I only. The proposed project would commence in 2011 and would be completed by 2033, for a total construction duration of 22 years. *Table 5.9-16* presents the heavy construction equipment assumptions for each construction stage.

The additional worker and construction-related truck trips to and from the project site would potentially affect traffic operations at project area intersections during peak hours. Potential constructed-related traffic impacts are considered adverse, but less than significant because the increased traffic generation during peak hours would be temporary and intermittent during the construction periods. However, in order to avoid hazards or short-term delay, mitigation is provided for short-term construction traffic impacts (see *Section 5.9.5, Mitigation Measures, Mitigation Measure 5.9-f*). This measure requires a traffic control plan for each phase of the project which will serve to eliminate any potential hazards to surrounding roadways due to abnormally high traffic into or out of the site for a concentrated period of time.

Would the project result in a change in air traffic patterns, including either an increase in traffic levels or a change in location that results in substantial safety risks?

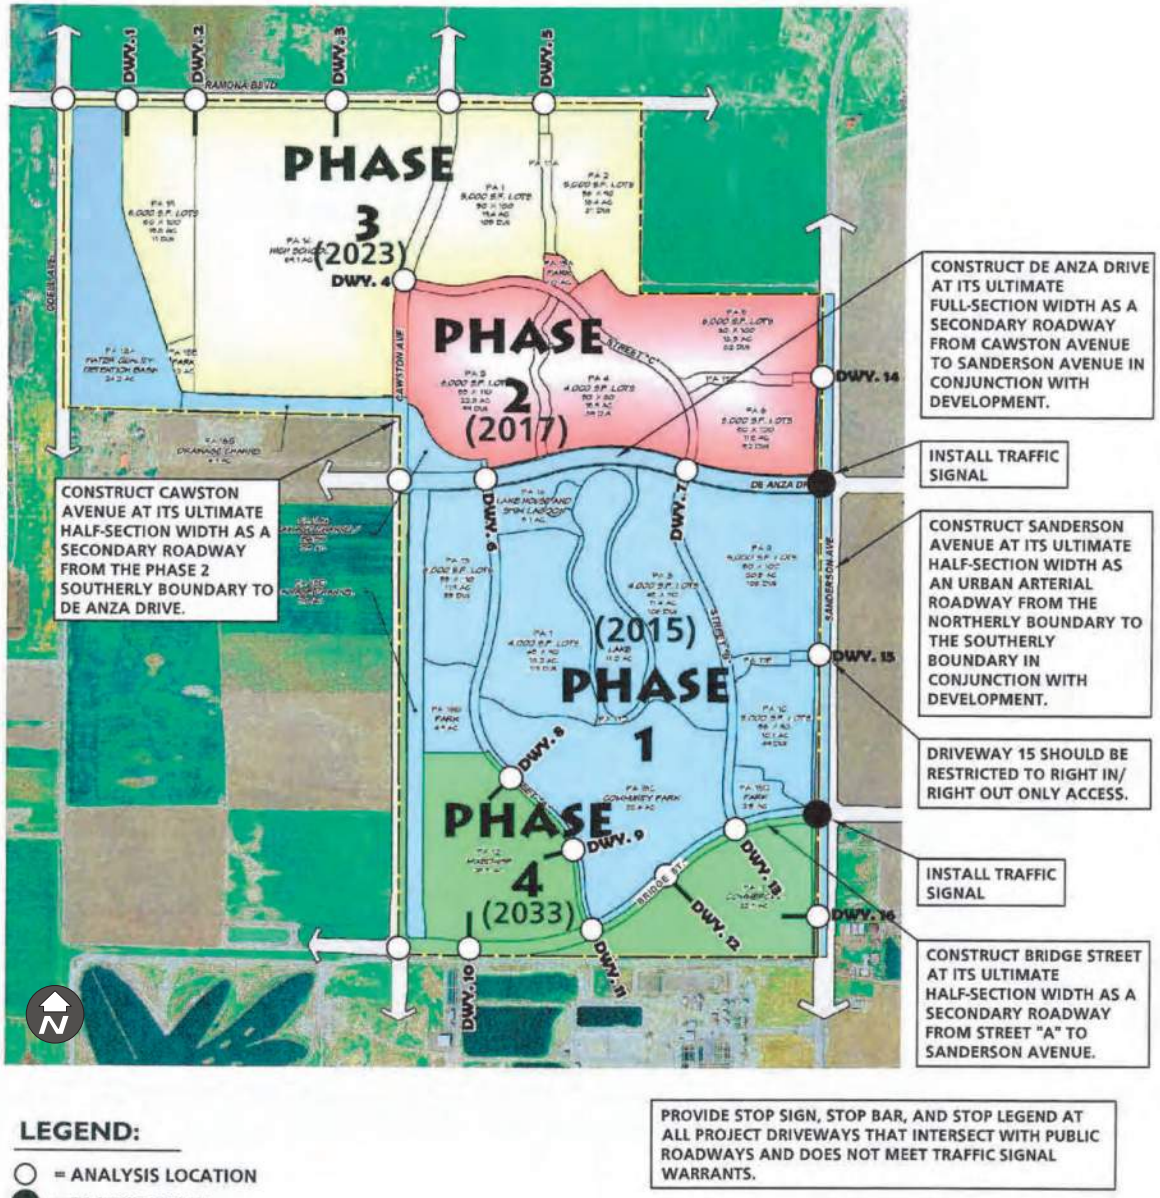
The proposed residential and commercial/retail structures would not impede existing air traffic navigational patterns or cause a change in the location of existing airport facilities in the region. Therefore, no impacts related to air traffic patterns would occur.

Would the project substantially increase hazards due to a design feature (e.g., sharp curves or dangerous intersections) or incompatible uses (e.g., farm equipment)?

Site access for the proposed development would be provided via a total of 17 driveways including seven full access driveways taking access from Odell Avenue, Cawston Avenue, Sanderson Avenue, Ramona Boulevard South, Bridge Street and De Anza Drive. The location of all driveways and traffic signal installations are shown below on *Figures 5.9-5* through *5.9-8*.

The proposed project provides appropriate access points and interior circulation patterns to ensure that adequate access and circulation is provided to and throughout the development. Site distance at each project access point would be reviewed to ensure standard Caltrans and City of San Jacinto sight distance requirements are provided by the project to avoid potential dangerous intersections. In addition, stop sign, stop bar, and stop legends would be provided at all project

driveways that intersect with public roadways (those not meeting traffic signal warrants), and on-site traffic signing and striping would be implemented in conjunction with detailed construction plans for the project site to ensure that the project provides adequate and safe site access and circulation, which meets minimum design standards applicable to the proposed development.



Mitigation measures that address project-related and cumulative traffic volume impacts to the surrounding street network will ensure that site access from the adjacent street system is maintained at acceptable levels to ensure that adequate and safe access and circulation is provided to the site (see *Section 5.9.5, Mitigation Measures, Mitigation Measures 5.9-a* through *5.9-f*).

Would the project result in inadequate emergency access?

As discussed above, the project will provide a total of 17 driveways including seven full access driveways and provides interior circulation patterns to ensure that adequate access and circulation is provided to and throughout the development. Therefore, no significant impacts related to emergency access would occur.

Would the project result in inadequate parking capacity?

The project is designed to have adequate parking for the proposed commercial, recreational and residential facilities. Parking requirements are set forth in the Villages of San Jacinto Specific Plan for each Planning Area within the development. Adherence to the project development standards will ensure that there is adequate parking for each proposed land use. The school facility, if built, is subject to the standards for parking adopted by the San Jacinto Unified School District.

Would the project conflict with adopted policies, plans, or programs supporting alternative transportation (e.g., bus turnouts, bicycle racks)?

There is currently no bus routes located on or near the project site. Local transit service is provided by the Riverside Transit Agency (RTA) with the nearest route (Route 31) traveling north-south through the City on State Street approximately two miles east of the site. Bus stops and or turnouts could be provided in the future, should RTA decide to locate a route adjacent to the site. One of the goals of the project is to develop a circulation system that meets projected traffic volumes and accommodates a variety of transportation modes and encourages alternatives to automobile use within the community. Design features include a series of landscaped paseos that will serve as pedestrian linkages between land uses. Pedestrian friendly design is encouraged for the mixed use and commercial portions of the project as well. Therefore, the project will not conflict with any adopted policies supporting alternative transportation.

5.9.5 Mitigation Measures

The following measures are site specific circulation and access requirements for each phase of the proposed project.

Phase I

5.9-a The following measures shall be implemented prior to issuance of the first residential and commercial building permits and as depicted on *Figure 5.9-5*:

- Construct Sanderson Avenue at its ultimate half-section width as an Urban Arterial roadway from the project's northerly boundary to the project's southerly boundary in conjunction with development.
- Construct De Anza Drive at its ultimate full-section width as a secondary roadway from Cawston Avenue to Sanderson Avenue in conjunction with development.
- Construct Bridge Street at its ultimate half-section width as a secondary roadway from Street "A" to Sanderson Avenue.
- Construct Cawston Avenue at its ultimate half-section width as a secondary roadway from the Phase II southerly boundary to De Anza Drive.
- Participate in fair share fees to construct a traffic signal at the following intersection in conjunction with Phase I of the development:
    - Sanderson Avenue (NS) at:
        - De Anza Drive (EW).

- Construct a traffic signal at the following intersection in conjunction with Phase I of the development:
  - Sanderson Avenue (NS) at:
    - Bridge Street (EW).
- Provide stop sign, stop bar, and stop legend at all project driveways that intersect with public roadways and do not meet traffic signal warrants.
- Driveway 15 shall be restricted to right in/right out only access.
- Sight distance at each project access shall be reviewed with respect to standard Caltrans and City of San Jacinto sight distance standards at the time of preparation of final grading landscape and street improvement plans.
- On-site traffic signing and striping shall be implemented in conjunction with detailed construction plans for the project site.

Phase II

5.9-b The following measures shall be implemented prior to issuance of the 432nd residential permit, any additional commercial building permits and as depicted on *Figure 5.9-6*:

- Construct Cawston Avenue at its ultimate full-section width as a secondary roadway along the Phase II Cawston Avenue boundaries in conjunction with Phase II of the development.
- Driveway 14 shall be restricted to right in/right out only access.
- Provide stop sign, stop bar, and stop legend at all project driveways that intersect with public roadways and do not meet traffic signal warrants.
- Sight distance at each project access shall be reviewed with respect to standard Caltrans and City of San Jacinto sight distance standards at the time of preparation of final grading landscape and street improvement plans.
- On-site traffic signing and striping shall be implemented in conjunction with detailed construction plans for the project site.

Phase III

5.9-c The following measures shall be implemented prior to issuance of the 754th residential permit, the high school, any additional commercial building permits and as depicted on *Figure 5.9-7*:

- Construct Odell Avenue at its ultimate half-section width as a secondary roadway from Ramona Boulevard to the project's southerly boundary in conjunction with Phase III development.
- Construct Cawston Avenue at its ultimate full-section width as a secondary roadway from Ramona Boulevard to the Phase II northerly boundary in conjunction with Phase III development.
- Construct Ramona Boulevard at its ultimate half-section width as a secondary roadway from Odell Avenue to Sanderson Avenue in conjunction with Phase III development.
- Driveway 5 at Ramona Boulevard shall be restricted to right in/right out only access.
- Participate in fair share fees to construct a traffic signal at the following intersection in conjunction with Phase III of the development:
    - Cawston Avenue (NS) at:
        - Ramona Boulevard (EW).
- Provide stop sign, stop bar, and stop legend at all project driveways that intersect with public roadways and do not meet traffic signal warrants.
- Sight distance at each project access shall be reviewed with respect to standard Caltrans and City of San Jacinto sight distance standards at the time of preparation of final grading landscape and street improvement plans.
- On-site traffic signing and striping shall be implemented in conjunction with detailed construction plans for the project site.
- Construct secondary access for PA 19 as approved by the City Engineer.

Phase IV

5.9-d The following measures shall be implemented prior to issuance of the final remaining commercial building permits and as depicted on *Figure 5.9-8*:

- Construct Cawston Avenue at its ultimate half-section width as a secondary roadway from Bridge Street to De Anza Drive in conjunction with Phase IV development.
- Construct Bridge Street at its ultimate full-section width as a secondary roadway from Cawston Avenue to Street "A" in conjunction with Phase IV development.
- Construct the remaining half of Bridge Street as a secondary roadway from Street "A" to Sanderson Avenue in conjunction with Phase IV development.
- Driveway 10 at Bridge Street shall be restricted to right in/right out only access.

- Driveway 12 at Bridge Street shall be restricted to right in/right out only access.
- Driveway 16 at Sanderson Avenue shall be restricted to right in/right out only access.
- Construct traffic signals at the following intersections in conjunction with Phase IV of the development:
  - Driveway 3 (NS) at:
    - Ramona Boulevard (EW) (Only if High School is constructed)
  - Street "A"/Driveway 11 (NS) at:
    - Bridge Street (EW)
  - Street "B"/Driveway 13 (NS) at:
    - Bridge Street (EW).
- Participate in fair share fees to construct a traffic signal at the following intersection in conjunction with Phase IV of the development:
  - Cawston Avenue (NS) at:
    - Bridge Street (EW).
- Provide stop sign, stop bar, and stop legend at all project driveways that intersect with public roadways and do not meet traffic signal warrants.
- Sight distance at each project access shall be reviewed with respect to standard Caltrans and City of San Jacinto sight distance standards at the time of preparation of final grading landscape and street improvement plans.
- On-site traffic signing and striping shall be implemented in conjunction with detailed construction plans for the project site.

5.9-e Because the project, along with many others in the area, is contributing to the city-wide need for street improvements, the project will need to contribute to the Riverside County TUMF and City of San Jacinto DIF programs. As discussed in *Section 5.9.2*, these fees are collected as part of a funding mechanism aimed at ensuring that local and regional highway capacity keeps pace with projected growth throughout the area. Eligible facilities for funding by the City's DIF program are identified on the City's Facility Needs List, which currently extends through the year 2020. *Table 5.9-17, Estimated TUMF and DIF Fee Calculations*, includes estimated fee calculations for the proposed project based on current fee rates.

Table 5.9-17
Estimated TUMF and DIF Fee Calculations

FEE REFERENCE	SINGLE FAMILY RESIDENTIAL ($ PER DU)	MULTI-FAMILY ($ PER DU)	COMMERCIAL ($ PER SQ FT)	OFFICE / SERVICE ($ PER SQ FT)	INDUSTRIAL ($ PER SQ FT)
San Jacinto Development Impact Fee: Streets and Roads Component (DIF)[1]	$1,468	$1,239	$0.17	$0.17	$0.14
San Jacinto Development Impact Fee: Traffic Signals (DIF)[1]	$256	$216	$0.03	$0.03	$0.02
Transportation Uniform Mitigation Fee (TUMF)	$9,812	$7,054	$9.99	$5.71	$1.84

[1] Non-residential uses under DIF have been converted to square footage for comparison purposes. Actual fee based upon acreage as follows:

Fee Type	Commercial	Office	Industrial
Streets and roads:	$7,226	$7,226	$6,102
Signals:	$1,260	$1,260	$1,064

Project With School Site

Program	Category	Unit Cost	Units	Total Cost	Program Totals
DIF - Streets and Roads	SFR	$1,468	1,016	$1,491,488

TUMF	SFR	$9,812	1,329	$13,040,148	
TUMF	Commercial	$9.99	281,572	$2,812,904	
TUMF	Office	$5.71	309,320	$1,766,217	
TUMF Totals					$17,619,269
Totals					**$20,025,578.19**

Notes:
A Floor Area Ratio (FAR) conversion rate of 25% was used for PA11 and 30% for PA12 for fee calculation purposes
Government Office is included in "Office" category for worse case scenario. Most fee programs do not charge a fee for actual government uses.

Many off-site circulation improvements required as a result of project impacts would be mitigated through participation in the TUMF fee program. Many of the off-site improvements that are needed will be planned, designed and constructed by the City, Riverside County Transportation Department, Riverside County Transportation Commission, other cities or a combination of the above.

In order to ensure that all off-site traffic improvements are constructed by the City (or the County/RCTC), prior to construction of specific project phases, the City shall ensure that the improvements are made to compensate for the project's contribution to off-site circulation issues. The project applicant's payment of TUMF and DIF fees will allow the financing mechanism to conduct such improvements.

5.9-f The contractor for each phase of the project shall be required to prepare and implement a traffic control plan (TCP) in order to monitor construction equipment, deliveries and construction worker traffic to eliminate any potential hazards to surrounding roadways due to abnormally high traffic into or out of the site for a concentrated period of time. Each traffic control plan shall outline when flagging operations may be necessary (during large construction equipment arrival or deportation, etc.).

5.9.6 Residual Impacts/Level of Significance after Mitigation

Access and On-Site Circulation

With implementation of the mitigation measures included in *Section 5.9.5, Mitigation Measures*, to ensure that adequate and safe site access and circulation design is provided for the proposed development, potential impacts relative to site access and circulation, and emergency access, would be less than significant.

Cumulative Traffic Impacts/ Regional Mitigation Programs

Implementation of the mitigation measures included in *Section 5.9.5, Mitigation Measures*, would ensure that regional traffic conditions do not dip below an acceptable LOS (LOS D) for existing plus project conditions. However, without completion of the Mid-County Parkway and SR-79 projects, the project would contribute to a cumulative significant impact. There is no feasible mitigation for this significant cumulative impact due to exceedance of General Plan roadway criteria (e.g., triple left turn lanes) and due to the uncertainty of obtaining adequate right-of-way for such measures. Therefore, because the City can not guarantee that regional improvements would be implemented prior to completion of the project, a significant unmitigable cumulative traffic impact would occur. That said, it should be noted that the unacceptable LOS conditions would occur with or without the project under cumulative conditions in the absence of the Mid-County Parkway and SR-79 improvements.

5.10 AIR QUALITY

5.10.1 Introduction and Methodology

This section evaluates short-term (construction) and long-term (operational) impacts to air quality that would potentially occur as a result of implementation of the proposed project. Impacts are evaluated for their significance based on the South Coast Air Quality Management District's (SCAQMD) enumerated environmental thresholds. Mitigation measures required to reduce impacts are recommended as appropriate. However, impacts associated with construction and operation would remain significant after mitigation. Technical information related to the analysis below is contained in *Appendix I* to this EIR.

5.10.2 Existing Conditions

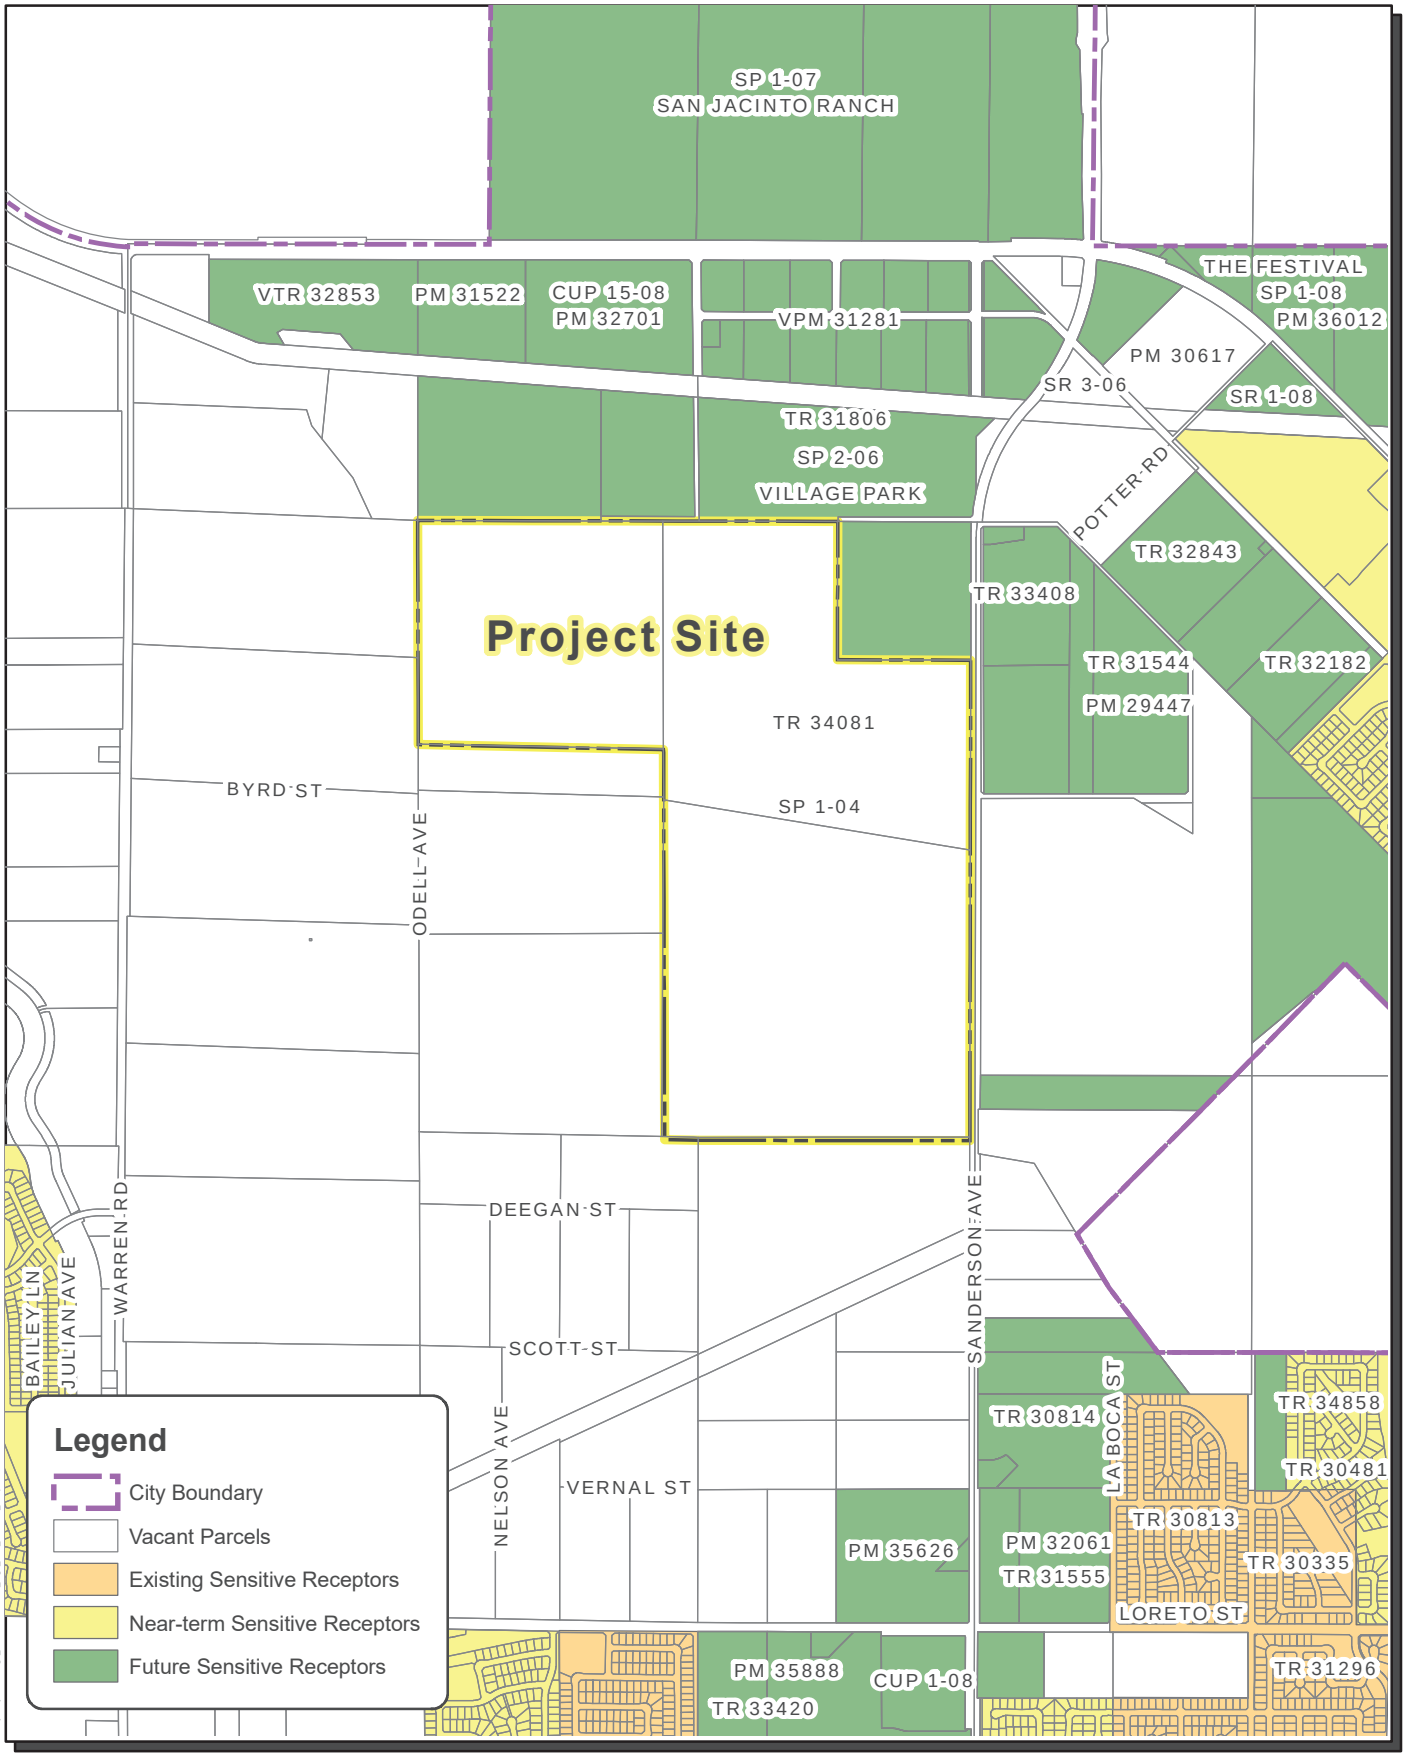
Regional Air Quality and Climate/Meteorology

The project site is located in western Riverside County within the City of San Jacinto, which lies at an elevation of approximately 1,567 feet. The natural topography of the project area can best be described as lying in valley lowland, intersected with rolling hills and surrounded by the Santa Ana Mountains to the west and the San Jacinto Mountains to the east. This project site is located within the South Coast Air Basin (SCAB), which includes all of Orange County and the non-desert portions of Los Angeles, Riverside, and San Bernardino counties. Air quality conditions in the SCAB are under the jurisdiction of the SCAQMD. The SCAQMD regulates stationary sources of pollution throughout its jurisdictional area. Direct emissions from motor vehicles are regulated by the California Air Resources Board (CARB).

Climate/Meteorology

Air quality in the planning area is not only affected by various emission sources (e.g., mobile, industry), but is also affected by atmospheric conditions such as wind speed, wind direction, temperature, and rainfall, etc. The SCAB's combination of topography, low mean mixing height, abundant sunshine, and emissions from one of the largest urban areas in the United States have historically resulted in some of the worst air pollution in the nation.

Although the SCAB has a semi-arid climate, air near the surface is generally moist because of the presence of a shallow marine layer. With very low average wind speeds, there is a limited capacity to disperse air contaminants horizontally. The dominant daily wind pattern is an onshore 8 to 12 miles per hour daytime breeze and an offshore 3 to 5 miles per hour nighttime breeze. The typical wind flow pattern fluctuates only with occasional winter storms, or strong northeasterly Santa Ana winds from the mountains and deserts northeast of the SCAB. Summer



wind flow patterns represent worst-case conditions, as this is the period of higher temperatures and more sunlight, which results in ozone formation.

The San Jacinto area climate is characterized by relatively low rainfall, with warm summers and mild winters. Annual precipitation averages about 13 inches, with over 70% of that falling between December and March. Average monthly temperatures range from a high of 98 degrees Fahrenheit in August to a low of 37 degrees Fahrenheit in December (City-Data.com, Accessed June 6, 2005).

During spring and early summer, pollution produced during any one day is typically blown out of the SCAB through mountain passes or lifted by warm, vertical currents adjacent to mountain slopes. The vertical dispersion of air pollutants in the SCAB is limited by temperature inversions in the atmosphere close to the earth's surface. The combination of stagnant wind conditions and low inversions produces the greatest pollutant concentrations. On days of no inversion or high wind speeds, ambient air pollutant concentrations are lowest. During periods of low inversions and low wind speeds, air pollutants generated in urbanized areas are transported predominantly onshore into Riverside and San Bernardino counties. In the winter, the greatest pollution problems are carbon monoxide and nitrogen dioxide because of extremely low inversions and air stagnation during the night and early morning hours. In the summer, the longer daylight hours and the brighter sunshine combine to cause a reaction between hydrocarbons and oxides of nitrogen to form photochemical smog.

Air Quality Characteristics

Air quality varies as a direct function of the amount of pollutants emitted into the atmosphere, the size and topography of the air basin and the prevailing meteorological conditions. Air quality problems arise when the rate of pollutant emissions exceeds the rate of dispersion. Reduced visibility, eye irritation, and adverse health impacts upon those persons termed sensitive receptors are the most serious hazards of existing air quality conditions in the area. Sensitive receptors are those persons under 5 years of age, or older than 65, and/or persons with health problems; consequently sensitive receptors include hospitals, convalescent homes, schools, and retirement facilities. There are no sensitive receptors currently located adjacent to the proposed project site. However, some existing residential development is located south and southeast of the project site, and some residential developments are currently under construction to the southwest, southeast, south, and east of the proposed project site. Lastly, several parcels adjacent to the proposed project site to the north and northeast may include future residential development during the construction and operational phases of the proposed project. The existing, near-term (under construction) and potential future sensitive receptors in the vicinity of the proposed project are shown in *Figure 5.10-1*.

0 500 1,000 2,000 Feet

Villages of San Jacinto EIR

Sensitive Receptors

FIGURE 5.10-1

INTENTIONALLY LEFT BLANK

Additional discussion of sensitive receptors in the vicinity of the project site is provided in the Localized Significance Thresholds Analysis in *Appendix I*.

Primary criteria pollutants are emitted directly from a source (e.g., an automobile) into the atmosphere and include volatile organic compounds (VOCs), oxides of nitrogen (NO_x), carbon monoxide (CO), sulfur oxides (SO_x) and particulate matter. Particulate matter is generally comprised of inert particles that become airborne, such as dust or ash. Particulate matter less than 10 microns in diameter is referred to as PM_{10}; particulate matter less than 2.5 microns in diameter is referred to as $PM_{2.5}$. VOCs are also a primary pollutant, but are not a "criteria" pollutant (see discussion below). Secondary pollutants are created by atmospheric chemical and photochemical reactions. Secondary pollutants include oxidants, ozone (O_3), particulate matter, and sulfate particulates.

Global Climate Change

The Earth's climate has undergone many changes during its history, ranging from ice ages to long periods of warmth. Natural factors such as volcanic eruptions, changes in the Earth's orbit, and the amount of energy from the sun have affected global temperatures and thus the Earth's climate. Climate change refers to any significant change in measures of climate (such as temperature, precipitation, or wind) lasting for an extended period (decades or longer) (EPA 2008a). The term climate change is often used interchangeably with the term global warming; however, the phrase "climate change" is preferred as it helps convey that there are other changes in addition to rising temperatures (NAS 2008).

Environmental Setting

The Greenhouse Effect and Greenhouse Gases (GHGs)

Heat retention within the atmosphere is an essential process to sustain life on Earth. The natural process through which heat is retained in the troposphere[1] is called the "greenhouse effect." The greenhouse effect traps heat in the troposphere through a three-fold process as follows: short-wave radiation emitted by the Sun is absorbed by the Earth; the Earth emits a portion of this energy in the form of long-wave radiation; and greenhouse gases (GHGs) in the upper atmosphere absorb this long-wave radiation and emit this long-wave radiation into space and toward the Earth. This "trapping" of the long-wave (thermal) radiation emitted back toward the Earth is the underlying process of the greenhouse effect. This natural process contributes to regulating the earth's temperature without which the temperature of the Earth would be about

[1] The troposphere is the bottom layer of the atmosphere, which varies in height from the Earth's surface to 10 to 12 kilometers).

zero degrees Fahrenheit (-18 degrees Celsius) instead of its present 57 degrees Fahrenheit (14 degrees Celsius) (NCDC 2008).

Gases that trap heat in the atmosphere are often called GHGs. Principal GHGs include carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), ozone (O_3), and water vapor (H_2O). Some GHGs, such as CO_2, CH_4, and N_2O, occur naturally and are emitted to the atmosphere through natural processes and human activities. Of these gases, CO_2 and CH_4 are emitted in the greatest quantities from human activities. Man-made GHGs, which have a much greater heat-absorption potential than CO_2, include fluorinated gases, such as hydrofluorocarbons (HFCs), perfluorocarbons (PFC), and sulfur hexafluoride (SF_6), which are byproducts of certain industrial processes. The major GHGs emitted by human activities remain in the atmosphere for periods ranging from decades to centuries; therefore, it is virtually certain that atmospheric concentrations of GHGs will continue to rise over the next few decades (EPA 2007).

It is generally agreed that human activity has been increasing the concentration of GHGs in the atmosphere (mostly carbon dioxide from combustion of coal, oil, and gas, and a few other trace gases) (NCDC 2008). The global atmospheric concentration of carbon dioxide has increased from a pre-industrial value of about 280 ppm to 379 ppm in 2005 (IPCC WGI 2007). Based on current rates of increase, carbon dioxide concentrations could reach between 490 to 1260 ppm by the end of the 21st century, 75 to 350% above the pre-industrial concentration (IPCC 2001).

A warming trend of approximately 1.0 to 1.7 degrees Fahrenheit occurred during the 20th century; warming occurred in both the northern and southern hemispheres, and over the oceans (IPCC WGI 2007). Most of the warming in recent decades is very likely the result of human activities (IPCC WGI 2007). There is much uncertainty, however, concerning the magnitude and rate of the warming. Specifically, the EPA notes that "important scientific questions remain about how much warming will occur, how fast it will occur, and how the warming will affect the rest of the climate system, including precipitation patterns and storms" (EPA 2007).

The effect each GHG has on climate change is measured as a combination of the volume or mass of its emissions, and the potential of a gas or aerosol to trap heat in the atmosphere, known as its global warming potential (GWP), and is expressed as a function of how much warming would be caused by the same mass of CO_2. Thus, GHG gas emissions are typically measured in terms of pounds or tons of "carbon dioxide equivalent" (CO_2E).

Contributions to Greenhouse Gas Emissions

Global

Anthropogenic GHG emissions worldwide in 2005 totaled approximately 41,100 CO_2 equivalent million metric tons ($MMTCO_2E$)[2] (CAIT 2009). Six countries—China, United States, Russian Federation, India, Japan, Brazil—and the European Community accounted for approximately 60% of the total global emissions, approximately 25,000 $MMTCO_2E$ (CAIT 2009).

United States

The United States was the second highest producer of GHG emissions in 2005. The primary GHG emitted by human activities in the United States was CO_2, representing approximately 84% of total GHG emissions. Carbon dioxide from fossil fuel combustion, the largest source of United States GHG emissions, accounted for approximately 80% of United States GHG emissions (EPA 2008b).

State of California

According to the 2004 GHG inventory data compiled by CARB for the California 1990 GHG emissions inventory, California emitted emissions of 484 $MMTCO_2E$, including emission resulting from out-of-state electrical generation (CARB 2007b). The primary contributors to GHG emissions in California are transportation, electric power production from both in-state and out-of-state sources, industry, agriculture and forestry, and other sources, which include commercial and residential activities. These primary contributors to California's GHG emissions and their relative contributions in 2004 are presented in *Table 5.10-1, GHG Sources in California*.

[2] The CO_2 equivalent emissions on a global or national scale are commonly expressed as "million metric tons of carbon dioxide equivalent ($MMTCO_2E$)" The carbon dioxide equivalent for a gas is derived by multiplying the tons of the gas by the associated GWP, such that $MMTCO_2E$ = (million metric tons of a GHG) x (GWP of the GHG). For example, the GWP for methane is 21. This means that emissions of one million metric tons of methane are equivalent to emissions of 21 million metric tons of CO_2.

Table 5.10-1
GHG Sources in California [1]

Source Category	Annual GHG Emissions ($MMTCO_2E$) [a]	Percent of Total	Annual GHG Emissions ($MMTCO_2E$) [b]	Percent of Total
Agriculture	27.9	5.8%	27.9	6.6%
Commercial Uses	12.8	2.6%	12.8	3.0%
Electricity Generation	119.8	24.7%	58.5	13.8%
Forestry (excluding sinks)	0.2	0.0%	0.2	0.0%
Industrial Uses	96.2	19.9%	96.2	22.7%
Residential Uses	29.1	6.0%	29.1	6.9%
Transportation	182.4	37.7%	182.4	43.1%
Other [c]	16.0	3.3%	16.0	3.8%
Totals	**484.4**	**100.0%**	**423.1**	**100.0%**

[1] SOURCES: CARB 2007
[a] Includes emissions associated with imported electricity, which account for 61.3 $MMTCO_2E$ annually
[b] Excludes emissions associated with imported electricity
[c] Unspecified combustion and use of ozone-depleting substances

Potential Effects of Human Activity on Climate Change

Globally, climate change has the potential to impact numerous environmental resources though uncertain impacts related to future air temperatures and precipitation patterns. Scientific modeling predicts that continued emissions of GHGs at or above current rates would induce more extreme climate changes during the 21st century than were observed during the 20th century. A warming of about 0.2 degrees Celsius (0.36 degrees Fahrenheit) per decade is projected, and there are identifiable signs that global warming could be taking place, including substantial ice loss in the Arctic (IPCC WGI 2007).

However, the scientific understanding of the effect of GHG emissions, particulate matter, and aerosols on global climate trends remains uncertain. In addition to uncertainties about the extent to which human activity rather than solar or volcanic activity is responsible for increasing warming, there is also evidence that some human activity has cooling rather than warming effects (IPCC 2001).

Below is a summary of some of the potential effects reported by an array of studies that could be experienced in California as a result of global warming and climate change.

Air Quality

Higher temperatures, conducive to air pollution formation, could worsen air quality in California. Climate change may increase the concentration of ground-level ozone, but the magnitude of the effect, and therefore its indirect effects, are uncertain. For other pollutants, the effects of climate

change and/or weather are less well studied, and even less well understood. If higher temperatures are accompanied by drier conditions, the potential for large wildfires could increase, which, in turn, would further worsen air quality. However, if higher temperatures are accompanied by wetter, rather than drier conditions, the rains would tend to temporarily clear the air of particulate pollution and reduce the incidence of large wildfires, thus ameliorating the pollution associated with wildfires. Additionally, severe heat accompanied by drier conditions and poor air quality could increase the number of heat-related deaths, illnesses, and asthma attacks throughout the state (CCCC 2006).

Water Supply

Uncertainty remains with respect to the overall impact of global climate change on future water supplies in California. Studies have found that, "considerable uncertainty about precise impacts of climate change on California hydrology and water resources will remain until we have more precise and consistent information about how precipitation patterns, timing, and intensity will change" (Kiparsky and Gleck 2003). Even assuming that climate change leads to long-term increases in precipitation, analysis of the impact of climate change is further complicated by the fact that no studies have identified or quantified the runoff impacts such an increase in precipitation would have in particular watersheds (CCCC 2006). Also, little is known about how groundwater recharge and water quality will be affected. Higher rainfall could lead to greater groundwater recharge, although reductions in spring runoff and higher evapotranspiration could reduce the amount of water available for recharge (CCCC 2006).

The California Department of Water Resources report on climate change and effects on the State Water Project, the Central Valley Project, and the Sacramento-San Joaquin Delta concludes that "climate change will likely have a significant effect on California's future water resources [and] future water demand," yet it also reports that much uncertainty about future water demand remains (DWR 2006). Still, changes in water supply are expected to occur, and many regional studies have shown that large changes in the reliability of water yields from reservoirs could result from only small changes in inflows (Kiparsky and Gleck 2003).

Hydrology

As discussed above, climate changes could potentially affect: the amount of snowfall, rainfall and snow pack; the intensity and frequency of storms; flood hydrographs (flash floods, rain or snow events, coincidental high tide and high runoff events); sea level rise and coastal flooding; coastal erosion; and the potential for salt water intrusion. A rise in sea levels could result in coastal flooding and erosion and could jeopardize California's water supply. Increased storm intensity and frequency could affect the ability of flood-control facilities, including levees, to handle storm events.

Agriculture

California has a $30 billion agricultural industry that produces half the country's fruits and vegetables. Higher CO_2 levels can stimulate plant production and increase plant water-use efficiency. However, if temperatures rise and drier conditions prevail, water demand could increase; crop-yield could be threatened by a less reliable water supply; and greater ozone pollution could render plants more susceptible to pest and disease outbreaks (CCCC 2006).

Ecosystems and Wildlife

Increases in global temperatures and the potential resulting changes in weather patterns could have ecological effects on a global and local scale. Soil moisture is likely to decline in many regions, intense rainstorms are likely to become more frequent, and sea level could rise as much as two feet along most of the United States coast. Rising temperatures could have four major impacts on plants and animals: (1) timing of ecological events; (2) geographic range; (3) species' composition within communities; and (4) ecosystem processes such as carbon cycling and storage (Parmesan and Galbraith 2004).

Regulatory Setting

Federal

The federal Clean Air Act, passed in 1970 and last amended in 1990, forms the basis for the national air pollution control effort. The EPA is responsible for implementing most aspects of the Clean Air Act, which include National Ambient Air Quality Standards (NAAQS) for major air pollutants, hazardous air pollutant standards, approval of state attainment plans, motor vehicle emission standards, stationary source emission standards and permits, acid rain control measures, stratospheric ozone protection, and enforcement provisions. NAAQS are established for "criteria pollutants" under the Clean Air Act, which are O_3, CO, nitrogen dioxide (NO_2), sulfur dioxide (SO_2), PM_{10}, $PM_{2.5}$, and lead (Pb).

The NAAQS describe acceptable air quality conditions designed to protect the health and welfare of the citizens of the nation; these NAAQS may not be exceeded more than once a year, except annual standards, which may never be exceeded. The Clean Air Act requires the EPA to reassess the NAAQS at least every 5 years to determine whether adopted standards are adequate to protect public health based on current scientific evidence. States with areas that exceed the NAAQS must prepare a State Implementation Plan that demonstrates how those areas will attain the standards within mandated time frames.

State

The Clean Air Act delegates the regulation of air pollution control and the enforcement of the NAAQS to the states. In California, the task of air quality management and regulation has been legislatively granted to the California Air Resources Board (CARB), with subsidiary responsibilities assigned to AQMDs and air pollution control districts at the regional and county levels. CARB, which became part of the California Environmental Protection Agency (Cal-EPA) in 1991, is responsible for ensuring implementation of the California Clean Air Act (CCAA) of 1988, responding to the federal Clean Air Act, and regulating emissions from motor vehicles and consumer products.

CARB has established California Ambient Air Quality Standards (CAAQS), which are more restrictive than the NAAQS, consistent with the Clean Air Act, which requires state regulations to be at least as restrictive as the federal requirements. The CAAQS describe adverse conditions; that is, pollution levels must be below these standards before a basin can attain the standard. Air quality is considered in "attainment" if pollutant levels are continuously below the standards and violate the standards no more than once each year. The NAAQS and CAAQS are presented in *Table 5.10-2, California and National Ambient Air Quality Standards*.

Table 5.10-2
California and National Ambient Air Quality Standards

Pollutant	Averaging Time	California Standards [a,c]	National Standards [b]	
			Primary [c,d]	Secondary [c,e]
Ozone (O_3)	1-hour	0.09 ppm (180 µg/m^3)	—	Same as primary
	8-hour	0.070 ppm (137 µg/m^3)	0.075 ppm (147 µg/m^3)	Same as primary
Carbon monoxide (CO)	8-hour	9.0 ppm (10 mg/m^3)	9 ppm (10 mg/m^3)	—
	1-hour	20 ppm (23 mg/m^3)	35 ppm (40 mg/m^3)	—
Nitrogen dioxide (NO_2)	Annual	0.030 ppm (57 µg/m^3)	0.053 ppm (100 µg/m^3)	Same as primary
	1-hour	0.18 ppm (339 µg/m^3)	—	—
Sulfur dioxide (SO_2)	Annual	—	0.030 ppm (80 µg/m^3)	—
	24-hour	0.04 ppm (105 µg/m^3)	0.14 ppm (365 µg/m^3)	—
	3-hour	—	—	0.5 ppm (1,300 µg/m^3)
	1-hour	0.25 ppm (655 µg/m^3)	—	—
Respirable Particulate Matter (PM_{10})	Annual	20 µg/m^3 *	—	Same as primary
	24-hour	50 µg/m^3	150 µg/m^3	Same as primary
Fine Particulate Matter ($PM_{2.5}$)	Annual	12 µg/m^3 **	15.0 µg/m^3	Same as primary
	24-hour	—	35 µg/m^3	Same as primary

Table 5.10-2 (Continued)

Pollutant	Averaging Time	California Standards [a,c]	National Standards [b]	
			Primary [c,d]	Secondary [c,e]
Lead	30-day	1.5 µg/m^3	—	—
	Quarterly	—	1.5 µg/m^3	Same as primary
Hydrogen sulfide	1-hour	0.03 ppm (42 µg/m^3)	—	—
Vinyl chloride	24-Hour	0.01 ppm (26 µg/m^3)	—	—
Sulfates	24-hour	25 µg/m^3	—	—
Visibility reducing particles [f]	8-hour (10:00 a.m. to 6:00 p.m. PST)	In sufficient amount to produce an extinction coefficient of 0.23 per kilometer due to particles when the relative humidity is less than 70%.	—	—

SOURCE: CARB 2008

a. California standards for O_3, CO, SO_2 (1 hour), NO_2, PM_{10}, $PM_{2.5}$, and visibility reducing particles, are values that are not to be exceeded. The standards for SO_2 (24-hour), sulfates, lead, hydrogen sulfide, and vinyl chloride standards are not to be equaled or exceeded.

b. National standards (other than ozone, particulate matter, and those based on annual averages or annual arithmetic mean) are not to be exceeded more than once a year. The ozone standard is attained when the fourth highest 8-hour concentration in a year, averaged over 3 years, is equal to or less than the standard. For PM_{10}, the 24-hour standard is attained when the expected number of days per calendar year with a 24-hour average concentration above 150 µg/m^3 is equal to or less than one. For $PM_{2.5}$, the 24-hour standard is attained when 98% of the daily concentrations, averaged over 3 years, are equal to or less than the standard.

c. Concentration expressed first in units in which it was promulgated. Equivalent units given in parenthesis are based on a reference temperature of 25°C and a reference pressure of 760 mm of mercury (1,013.2 millibars). All measurements of air quality are to be corrected to a reference temperature of 25°C and a reference pressure of 760 mm of mercury; ppm in this table refers to ppm by volume, or micromoles of pollutant per mole of gas.

d. National Primary Standards: The levels of air quality necessary, with an adequate margin of safety to protect the public health.

e. National Secondary Standards: The levels of air quality necessary to protect the public welfare from any known or anticipated adverse effects of a pollutant.

f This standard is intended to limit the frequency and severity of visibility impairment due to regional haze and is equivalent to a 10-mile nominal visual range when relative humidity is less than 70%.

* Measured as an arithmetic mean. New standard promulgated by the ARB on June 20, 2002

** New standard promulgated by the ARB on June 20, 2002

Local

While CARB is responsible for the regulation of mobile emission sources within the state, local AQMDs and air pollution control districts are responsible for enforcing standards and regulating stationary sources. The SCAQMD is the regional agency responsible for the regulation and enforcement of federal, state, and local air pollution control regulations in the SCAB, where the proposed project is located. The SCAQMD operates monitoring stations in the SCAB, develops rules and regulations for stationary sources and equipment, prepares emissions inventory and air quality management planning documents, and conducts source testing and inspections. The SCAQMD's Air Quality Management Plans (AQMP) include control measures and strategies to be implemented to attain state and federal ambient air quality standards in the SCAB. The SCAQMD then implements these control measures as regulations to control or reduce criteria pollutant emissions from stationary sources or equipment.

The South Coast Air Quality Management District Governing Board adopted the 2003 AQMP on August 1, 2003. The 2003 AQMP updates the attainment demonstration for the federal standards for O_3 and PM_{10}; replaces the 1997 attainment demonstration for the federal CO standard,

provides a basis for a maintenance plan for CO for the future; and updates the maintenance plan for the federal NO_2 standard that the SCAB has met since 1992. The South Coast Air Quality Management District Governing Board adopted the 2007 AQMP on June 1, 2007. The 2007 AQMP includes the same updates as the 2003 AQMP and also incorporates significant new scientific data, primarily in the form of updated emissions inventories, ambient measurements, new meteorological episodes and new air quality modeling tools. As part of the 2007 AQMP, the SCAQMD request that EPA "bump up" the O_3 nonattainment status from severe to extreme to allow additional time for the SCAB to achieve attainment with the federal standard. The additional time would provide for implementation of state and federal measures that apply to sources over which the SCAQMD does not have control. The 2007 AQMP has been approved by CARB but is undergoing review by EPA.

Emissions that would result from mobile, stationary, and areas sources during construction and operation of the proposed project are subject to the rules and regulations of the SCAQMD. The SCAQMD rules applicable to the proposed project may include the following.

Rule 403 (Fugitive Dust)

This rule requires fugitive dust sources to implement Best Available Control Measures for all sources and all forms of visible particulate matter are prohibited from crossing any property line. SCAQMD Rule 403 is intended to reduce PM_{10} emissions from any transportation, handling, construction, or storage activity that has the potential to generate fugitive dust (see also Rule 1186).

Rule 431.2 (Sulfur Content of Liquid Fuels)

The purpose of this rule is to limit the sulfur content in diesel and other liquid fuels for the purpose of both reducing the formation of SO_x and particulates during combustion and to enable the use of add-on control devices for diesel fueled internal combustion engines. The rule applies to all refiners, importers, and other fuel suppliers such as distributors, marketers and retailers, as well as to users of diesel, low-sulfur diesel, and other liquid fuels for stationary source applications in the District. The rule also affects diesel fuel supplied for mobile source applications.

Rule 445 (Wood Burning Devices)

This rule prohibits the installation of permanently installed wood-burning devices into any new development and restricts the installation of wood-burning devices into existing development to specific devices, primarily those certified by EPA.

Rule 1113 (Architectural Coatings)

This rule requires manufacturers, distributors, and end-users of architectural and industrial maintenance coatings to reduce VOC emissions from the use of these coatings, primarily by placing limits on the VOC content of various coating categories.

Rule 1121 (Control of Nitrogen Oxides from Residential Type, Natural Gas-Fired Water Heaters)

This rule prescribes NOx emission limits for natural gas-fired water heaters with heat input rates less than 75,000 BTU per hour. It applies to manufacturers, distributors, retailers, and installers of natural gas-fired water heaters.

Rule 1146.2 (Emissions of Oxides of Nitrogen from Large Water Heaters and Small Boilers and Process Heaters)

This rule requires manufacturers, distributors, retailers, refurbishers, installers and operators of new and existing units to reduce NOx emissions from natural gas-fired water heaters, boilers, and process heaters as defined in this rule.

Rule 1186 (PM10 Emissions from Paved and Unpaved Roads, and Livestock Operations)

This rule applies to owners and operators of paved and unpaved roads and livestock operations. The rule is intended to reduce PM10 emissions by requiring the clean-up of material deposited onto paved roads, use of certified street sweeping equipment, and treatment of high-use unpaved roads (see also Rule 403).

Greenhouse Gas Regulatory Programs

International Activities

Kyoto Protocol

The United States is, and has been, a participant in the United Nations Framework Convention on Climate Change (UNFCCC) since it was signed on March 21, 1994. The Kyoto Protocol is a treaty made under the UNFCCC and was the first international agreement to regulate GHG emissions. The original Kyoto Protocol was negotiated in December 1997 and came into force on February 16, 2005. As of January 2009, 183 countries and the European Economic Community (EEC) have ratified the agreement (UNFCCC 2009). The goal of the protocol is to achieve overall emissions reduction targets for six GHGs by the period 2008 to 2012.

Federal Activities

Massachusetts vs. EPA

To date, the EPA has not regulated GHGs under the Clean Air Act based on the assertion that "(1) the Act does not authorize it to issue mandatory regulations to address global climate change, and (2) even if it had the authority to set GHG emission standards, it would have been unwise to do so at that time because a causal link between GHGs and the increase in global surface air temperatures was not unequivocally established."[3] In *Massachusetts v. EPA*, however, the Supreme Court held that EPA has the statutory authority under Section 202 of the Clean Air Act to regulate GHGs from new motor vehicles because GHGs meet the Clean Air Act definition of an air pollutant.[4] The court did not hold that the EPA was required to regulate GHG emissions; however, it indicated that the agency must decide whether GHGs from motor vehicles cause or contribute to air pollution that is reasonably anticipated to endanger public health or welfare. Upon the final decision, President Bush signed Executive Order 13432 on May 14, 2007, directing the EPA, along with the Departments of Transportation, Energy, and Agriculture, to initiate a regulatory process that responds to the Supreme Court's decision.

In *Massachusetts v. EPA*, the Supreme Court directed the Administrator to determine whether GHG emissions from new motor vehicles cause or contribute to air pollution that may reasonably be anticipated to endanger public health or welfare, or whether the science is too uncertain to make a reasoned decision. In making these decisions, the Administrator is required to follow the language of Section 202(a) of the Clean Air Act. On April 17, 2009, the Administrator signed a proposal with two distinct findings regarding greenhouse gases under section 202(a) of the Clean Air Act:

- The Administrator is proposing to find that the current and projected concentrations of the mix of 6 key greenhouse gases—CO_2, CH_4, N_2O, HFCs, PFCs, and SF_6—in the atmosphere threaten the public health and welfare of current and future generations. This is referred to as the endangerment finding.

- The Administrator is further proposing to find that the combined emissions of CO_2, CH_4, N_2O, and HFCs from new motor vehicles and motor vehicle engines contribute to the atmospheric concentrations of these key greenhouse gases and hence to the threat of climate change. This is referred to as the cause or contribute finding.

3 *Massachusetts et al. v. Environmental Protection Agency et al*., 549 U.S. 497 (2007).
4 Ibid.

Energy Independence and Security Act

On December 19, 2007, President Bush signed the Energy Independence and Security Act of 2007. Among other key measures, the Act would do the following, which would aid in the reduction of national GHG emissions:

1. Increase the supply of alternative fuel sources by setting a mandatory Renewable Fuel Standard (RFS) requiring fuel producers to use at least 36 billion gallons of biofuel in 2022
2. Set a target of 35 miles per gallon for the combined fleet of cars and light trucks by Model Year 2020, directs National Highway Traffic Safety Administration to establish a fuel economy program for medium- and heavy-duty trucks and create a separate fuel economy standard for work trucks
3. Prescribe or revise standards affecting regional efficiency for heating and cooling products, procedures for new or amended standards, energy conservation, energy efficiency labeling for consumer electronic products, residential boiler efficiency, electric motor efficiency, and home appliances.

State of California

AB 1493

In a response to the transportation sector accounting for more than half of California's CO_2 emissions, Assembly Bill 1493 (AB 1493, Pavley) was enacted on July 22, 2002. AB 1493 required CARB to set GHG emission standards for passenger vehicles, light-duty trucks, and other vehicles determined by the state board to be vehicles whose primary use is noncommercial personal transportation in the state. The bill required that CARB set the GHG emission standards for motor vehicles manufactured in 2009 and all subsequent model years. CARB adopted the standards in September 2004. When fully phased in, the near-term (2009–2012) standards will result in a reduction of about 22% in GHG emissions compared to the emissions from the 2002 fleet, while the mid-term (2013–2016) standards will result in a reduction of about 30%.

In December 2004, these regulations were challenged in federal court by the Alliance of Automobile Manufacturers, which claimed that the law regulated vehicle fuel economy, a duty assigned to the federal government. Upon the U.S. Supreme Court's decision in *Massachusetts v. EPA*, the U.S. District Court for the Eastern District dismissed the case by the Alliance of Automobile Manufacturers in December 2007. However, before these regulations may go into effect, the EPA must grant California a waiver under the federal Clean Air Act, which ordinarily preempts state regulation of motor vehicle emission standards. On December 19, 2007, Stephen Johnson, the EPA Administrator, denied the waiver citing the need for a national approach to

reducing GHG emissions, the lack of a "need to meet compelling and extraordinary conditions," and the benefits to be achieved through the Energy Independence and Security Act of 2007 (Johnson 2007). The California Attorney General subsequently filed suit in January 2008 to overturn the administrator's decision. The Obama Administration has reevaluated the waiver, and the waiver was granted by Lisa Jackson, the EPA Administrator, on June 30, 2009.

SB 1078

Approved by Governor Davis in September 2002, Senate Bill 1078 (SB 1078, Sher) established the Renewal Portfolio Standard program, which requires an annual increase in renewable generation by the utilities equivalent to at least 1% of sales, with an aggregate goal of 20% by 2017. This goal was subsequently accelerated, requiring utilities to obtain 20% of their power from renewable sources by 2010 (see SB 107). (See also Executive Order S-14-08.)

Executive Order S-3-05

In June 2005, Governor Schwarzenegger established California's GHG emissions reduction targets in Executive Order S-3-05. The Executive Order established the following goals: GHG emissions should be reduced to 2000 levels by 2010; GHG emissions should be reduced to 1990 levels by 2020; and GHG emissions should be reduced to 80% below 1990 levels by 2050. The Secretary of CalEPA is required to coordinate efforts of various agencies in order to collectively and efficiently reduce GHGs. Representatives from several state agencies comprise the Climate Action Team. The Climate Action Team is responsible for implementing global warming emissions reduction programs. The Climate Action Team fulfilled its report requirements through the March 2006 Climate Action Team Report to Governor Schwarzenegger and the legislature (CAT 2006). A second biennial report was released in April 2009.

The 2009 Draft Climate Action Team Report expands on the policy oriented in the 2006 assessment. The 2009 report provides new information and scientific findings regarding the development of new climate and sea-level projections using new information and tools that have recently become available and evaluates climate change within the context of broader soil changes, such as land use changes and demographics. The 2009 report also identifies the need for additional research in several different aspects that affect climate change in order to support effective climate change strategies. The aspects of climate change that were discussed that need future research include vehicle and fuel technologies, land use and smart growth, electricity and natural gas, energy efficiency, renewable energy and reduced carbon energy sources, low GHG technologies for other sectors, carbon sequestration, terrestrial sequestration, geologic sequestration, economic impacts and considerations, social science, and environmental justice.

SB 107

Approved by Governor Schwarzenegger on September 26, 2006, Senate Bill 107 (SB 107, Simitian) requires investor-owned utilities such as Pacific Gas and Electric, Southern California Edison, and San Diego Gas and Electric, to generate 20% of their electricity from renewable sources by 2010. Previously, state law required that this target be achieved by 2017 (see SB 1078).

AB 32

In furtherance of the goals established in Executive Order S-3-05, the legislature enacted Assembly Bill 32 (AB 32, Nuñez and Pavley), the California Global Warming Solutions Act of 2006, which Governor Schwarzenegger signed on September 27, 2006. The GHG emissions limit is equivalent to the 1990 levels, which are to be achieved by 2020.

CARB was been assigned to carry out and develop the programs and requirements necessary to achieve the goals of AB 32. Under AB 32, CARB must adopt regulations requiring the reporting and verification of statewide GHG emissions. This program will be used to monitor and enforce compliance with the established standards. CARB is also required to adopt rules and regulations to achieve the maximum technologically feasible and cost-effective GHG emission reductions. AB 32 allows CARB to adopt market-based compliance mechanisms to meet the specified requirements. Finally, CARB is ultimately responsible for monitoring compliance and enforcing any rule, regulation, order, emission limitation, emission reduction measure, or market-based compliance mechanism adopted.

The first action under AB 32 resulted in the adoption of a report listing early action GHG emission reduction measures on June 21, 2007. The early actions include three specific GHG control rules. On October 25, 2007, CARB approved an additional six early action GHG reduction measures under AB 32. The original three adopted early action regulations meeting the narrow legal definition of "discrete early action GHG reduction measures" include:

- A low-carbon fuel standard to reduce the "carbon intensity" of California fuels
- Reduction of refrigerant losses from motor vehicle air conditioning system maintenance to restrict the sale of "do-it-yourself" automotive refrigerants
- Increased methane capture from landfills to require broader use of state-of-the-art methane capture technologies.

The additional six early action regulations, which were also considered "discrete early action GHG reduction measures," include:

1. Reduction of aerodynamic drag, and thereby fuel consumption, from existing trucks and trailers through retrofit technology
2. Reduction of auxiliary engine emissions of docked ships by requiring port electrification
3. Reduction of perfluorocarbons from the semiconductor industry
4. Reduction of propellants in consumer products (e.g., aerosols, tire inflators, and dust removal products)
5. Require that all tune-up, smog check and oil change mechanics ensure proper tire inflation as part of overall service in order to maintain fuel efficiency
6. Restriction on the use of sulfur hexafluoride (SF_6) from non-electricity sectors if viable alternatives are available.

As required under AB 32, on December 6, 2007, CARB approved the 1990 GHG emissions inventory, thereby establishing the emissions limit for 2020. The 2020 emissions limit was set at 427 MMT CO_2E. In addition to the 1990 emissions inventory, CARB also adopted regulations requiring mandatory reporting of GHGs for large facilities that account for 94% of GHG emissions from industrial and commercial stationary sources in California. About 800 separate sources that fall under the new reporting rules and include electricity generating facilities, electricity retail providers and power marketers, oil refineries, hydrogen plants, cement plants, cogeneration facilities, and other industrial sources that emit carbon dioxide in excess of specified thresholds.

On December 11, 2008, CARB approved the Scoping Plan to achieve the goals of AB 32. The Scoping Plan establishes an overall framework for the measures that will be adopted to reduce California's GHG emissions. The Scoping Plan evaluates opportunities for sector-specific reductions, integrates all CARB and Climate Action Team early actions and additional GHG reduction measures by both entities, identifies additional measures to be pursued as regulations, and outlines the role of a cap-and-trade program. Additional development of these measures and adoption of the appropriate regulations will occur over the next 2 years, becoming effective by January 1, 2012. The key elements of the Scoping Plan include (CARB 2008):

- Expanding and strengthening existing energy efficiency programs as well as building and appliance standards;
- Achieving a statewide renewables energy mix of 33%;
- Developing a California cap-and-trade program that links with other Western Climate Initiative partner programs to create a regional market system and caps sources contributing 85% of California's GHG emissions;

- Establishing targets for transportation-related GHG emissions for regions throughout California, and pursuing policies and incentives to achieve those targets;
- Adopting and implementing measures pursuant to existing state laws and policies, including California's clean car standards, goods movement measures, and the Low Carbon Fuel Standard; and
- Creating targeted fees, including a public goods charge on water use, fees on high global warming potential gases, and a fee to fund the administrative costs of the State of California's long term commitment to AB 32 implementation.

SB 1368

In September 2006, Governor Schwarzenegger signed SB 1368, which requires the CEC to develop and adopt regulations for GHG emissions performance standards for the long-term procurement of electricity by local publicly-owned utilities. These standards must be consistent with the standards adopted by the Public Utilities Commission. This effort will help to protect energy customers from financial risks associated with investments in carbon-intensive generation by allowing new capital investments in power plants whose GHG emissions are as low or lower than new combined-cycle natural gas plants, by requiring imported electricity to meet GHG performance standards in California and requiring that the standards be developed and adopted in a public process.

Executive Order S-1-07

Issued on January 18, 2007, Executive Order S-1-07 sets a declining Low Carbon Fuel Standard (LCFS) for GHG emissions measured in CO_2-equivalent gram per unit of fuel energy sold in California. The target of the LCFS is to reduce the carbon intensity of California passenger vehicle fuels by at least 10% by 2020. The carbon intensity measures the amount of GHG emissions in the lifecycle of a fuel, including extraction/feedstock production, processing, transportation, and final consumption, per unit of energy delivered. CARB adopted the implementing regulation in April 2009. The regulation is expected to increase the production of biofuels, including those from alternative sources such as algae, wood, and agricultural waste. In addition, the LCFS would drive the availability of plug-in hybrid, battery electric, and fuel-cell power motor vehicles. The LCFS is anticipated to replace 20% of the fuel used in motor vehicles with alternative fuels by 2020.

SB 97

In August 2007, the legislature enacted SB 97 (Dutton), which directs the Governor's Office of Planning and Research (OPR) to develop guidelines under CEQA for the mitigation of GHG emissions. OPR is to develop proposed guidelines by July 1, 2009, and the Natural Resources

Agency is directed to adopt guidelines by January 1, 2010. On April 13, 2009, OPR submitted to the Secretary for Natural Resources its proposed amendments to the state CEQA Guidelines. This bill also protects projects funded by the Highway Safety, Traffic Reduction, Air Quality and Port Security Bond Act of 2006, or the Disaster Preparedness and Flood Protection Bond Act of 2006 from claims of inadequate analysis of GHG as a legitimate cause of action. This latter provision will be repealed on January 1, 2010.

On June 19, 2008, OPR issued a technical advisory as interim guidance regarding the analysis of GHG emissions in CEQA documents (OPR 2008). The advisory indicated that a project's GHG emissions, including those associated with vehicular traffic, energy consumption, water usage, and construction activities, should be identified and estimated. The advisory further recommended that the lead agency determine significance of the impacts and impose all mitigation measures that are necessary to reduce GHG emissions to a less-than-significant level.

On April 13, 2009, OPR submitted to the Natural Resources Agency its proposed amendments to the state CEQA Guidelines relating to greenhouse gas emissions. On July 3, 2009, the Natural Resources Agency commenced the Administrative Procedure Act rulemaking process for certifying and adopting the proposed amendments, starting the public comment period. The Natural Resources Agency is directed to adopt guidelines by January 1, 2010.

SB 375

In August 2008, the legislature passed and on September 30, 2008, Governor Schwarzenegger signed SB 375 (Steinberg), which addresses GHG emissions associated with the transportation section through regional transportation and sustainability plans. By September 30, 2010, CARB will assign regional GHG reduction targets for the automobile and light truck sector for 2020 and 2035. The targets are required to consider the emission reductions associated with vehicle emission standards (see SB 1493), the composition of fuels (see Executive Order S-1-07), and other CARB-approved measures to reduce GHG emissions. Regional metropolitan planning organizations will be responsible for preparing a Sustainable Communities Strategy within the Regional Transportation Plan. The goal of the Sustainable Communities Strategy is to establish a development plan for the region, which, after considering transportation measures and policies, will achieve, if feasible, the GHG reduction targets. If a Sustainable Communities Strategy is unable to achieve the GHG reduction target, a metropolitan planning organization must prepare an Alternative Planning Strategy demonstrating how the GHG reduction target would be achieved through alternative development patterns, infrastructure, or additional transportation measures or policies. SB 375 provides incentives for streamlining CEQA requirements by substantially reducing the requirements for "transit priority projects," as specified in SB 375, and eliminating the analysis of the impacts of certain residential projects on global warming and the

growth-inducing impacts of those projects when the projects are consistent with the Sustainable Communities Strategy or Alternative Planning Strategy.

Executive Order S-13-08

Governor Schwarzenegger issued Executive Order S-13-08 on November 14, 2008. The Executive Order is intended to hasten California's response to the impacts of global climate change, particularly sea level rise. It directs state agencies to take specified actions to assess and plan for such impacts. It directs the Resource Agency, in cooperation with the California Department of Water Resources, CEC, California's coastal management agencies, and the Ocean Protection Council to request the National Academy of Sciences to prepare a Sea Level Rise Assessment Report by December 1, 2010. The Ocean Protection Council, California Department of Water Resources, and CEC, in cooperation with other state agencies are required to conduct a public workshop to gather information relevant to the Sea Level Rise Assessment Report. The Business, Transportation, and Housing Agency was ordered to assess the vulnerability of the state's transportation systems to sea level rise within 90 days of the order. The Office of Planning and Research and the Resources Agency are required to provide land use planning guidance related to sea level rise and other climate change impacts. The order also requires the other state agencies to develop adaptation strategies by June 9, 2009, to respond to the impacts of global climate change that are predicted to occur over the next 50 to 100 years.

Executive Order S-14-08

On November 17, 2008, Governor Schwarzenegger issued Executive Order S-14-08. This Executive Order focuses on the contribution of renewable energy sources to meet the electrical needs of California while reducing the GHG emissions from the electrical sector. The governor's order requires that all retail suppliers of electricity in California serve 33% of their load with renewable energy by 2020. Furthermore, the order directs state agencies to take appropriate actions to facilitate reaching this target. The Resources Agency, through collaboration with the CEC and Department of Fish and Game, is directed to lead this effort. Pursuant to a Memorandum of Understanding between the CEC and Department of Fish and Game creating the Renewable Energy Action Team, these agencies will create a "one-stop" process for permitting renewable energy power plants.

Pollution Constituents and Attainment Status

The significance of a pollutant concentration is determined by comparing it to state and/or federal ambient air quality standards, which represent the maximum allowable atmospheric concentrations of various pollutants which may occur and still protect public health and welfare, with a reasonable margin of safety. The EPA and CARB designate areas of California as having air quality better than (attainment) or worse than (nonattainment) the NAAQS/CAAQS.

The criteria pollutants of primary concern that are considered in this air quality assessment include O_3, CO, NO_2, PM_{10}, and $PM_{2.5}$. Although there are no ambient standards for VOCs or NO_x, they are important as precursors to O_3.

The criteria for nonattainment designation varies by pollutant. A system of monitoring stations which measure ambient air quality has been established to assist in the enforcement of the above-referenced standards. The following section describes the six criteria air pollutants and their attainment status according to both state and federal standards. *Table 5.10-3, South Coast Air Basin Attainment Classification*, shows the SCAB attainment designation/classification under the NAAQS and CAAQS.

Ozone

Ozone (O_3) is a secondary pollutant formed in the atmosphere by photochemical reactions of previously emitted pollutants, or precursors. These precursors are mainly NO_x and VOCs (also referred to as reactive organic compounds or gases [ROC or ROG]). The maximum effects of precursor emissions on O_3 concentrations usually occur several hours after they are emitted and many miles from the source. Ozone concentrations are highest during the warmer months and coincide with the seasons of maximum solar radiation. Ozone is a pungent, colorless gas typical of Southern California smog. Elevated ozone concentrations result in reduced lung function, particularly during vigorous physical activity. This health problem is particularly acute in sensitive receptors such as the sick, the elderly, and young children. Ozone levels peak during summer and early fall.

The entire SCAB is designated as a nonattainment area for both federal and state ozone standards. The EPA has classified the SCAB as a "severe" nonattainment area and has mandated that the SCAB achieve attainment by no later than 2021

Table 5.10-3
South Coast Air Basin Attainment Classification

Pollutant	Averaging Time	Designation/Classification
National		
Ozone (O_3)	8 hour	Nonattainment/severe
Nitrogen dioxide (NO_2)	Annual arithmetic mean	Attainment
Carbon monoxide (CO)	1 hour, 8 hour	Attainment
Sulfur dioxide (SO_2)	24 hour, annual arithmetic mean	Unclassifiable
Respirable particulate matter (PM_{10})	24 hour	Nonattainment/serious
Fine particulate matter ($PM_{2.5}$)	24 hour, annual arithmetic mean	Nonattainment
Lead (Pb)	Calendar quarter	Attainment
State [b]		
Ozone (O_3)	1 hour, 8 hour	Nonattainment[1]
Nitrogen dioxide (NO_2)	1 hour, Annual	Attainment[2]
Carbon monoxide (CO)	1 hour, 8 hour	Attainment

Table 5.10-3 (Continued)

Pollutant	Averaging Time	Designation/Classification
Sulfur dioxide (SO_2)	1 hour, 24 hour	Attainment
Respirable particulate matter (PM_{10})	24 hour, annual arithmetic mean	Nonattainment
Fine particulate matter ($PM_{2.5}$)	Annual arithmetic mean	Nonattainment
Lead (Pb)[3]	30 day average	Attainment
Sulfates (SO_4)	24 hour	Attainment
Hydrogen sulfide (H_2S)	1 hour	Unclassified
Vinyl chloride[3]	24 hour	Unclassified
Visibility-reducing particles	8 hour (10:00 a.m.–6:00 p.m.)	Unclassified

SOURCES: [a] EPA 2008, [b] CARB 2009.

1 CARB has not issued area classification based on the new state 8-hour standard. The previous classification for the 1-hour O3 standard was Extreme.

2 CARB has not issued area classification based on the new state 1-hour and annual standards.

3 CARB has identified Pb, vinyl chloride, and Toxic Air Contaminants with no threshold level of exposure for adverse health effects determined.

Carbon Monoxide

Carbon monoxide (CO) is formed by the incomplete combustion of fossil fuels, almost entirely from automobiles. It is a colorless, odorless gas that can cause dizziness, fatigue, and impairments to central nervous system functions.

The SCAB is designated as an attainment area for federal CO standards. Although western portions of the SCAB are considered "unclassifiable" under state CO standards, Riverside County has been designated by CARB to be an attainment area.

Nitrogen Oxides

Nitrogen dioxide (NO_2), a reddish brown gas, and nitric oxide (NO), a colorless, odorless gas, are formed from fuel combustion under high temperature or pressure. These compounds are referred to as oxides of nitrogen, or NO_x. NO_x is a primary component of the photochemical smog reaction. It also contributes to other pollution problems, including a high concentration of fine particulate matter, poor visibility, and acid deposition. NO_2 decreases lung function and may reduce resistance to infection.

The entire SCAB has not exceeded either federal or state standards for nitrogen dioxide in the past 5 years based published monitoring data. It is designated as an attainment area under the federal and state standards. The state NO_2 standard was revised in 2008, but new designations have not been adopted.

Sulfur Dioxide

Sulfur dioxide (SO_2) is a colorless irritating gas formed primarily from incomplete combustion of fuels containing sulfur. Industrial facilities also contribute to gaseous SO_2 levels. SO_2 irritates the respiratory tract, can injure lung tissue when combined with fine particulate matter, and reduces visibility and the level of sunlight.

The entire SCAB is in attainment with both federal and state sulfur dioxide standards.

Lead

Lead (Pb) is found in old paints and coatings, plumbing and a variety of other materials. Once in the blood stream, lead can cause damage to the brain, nervous system, and other body systems. Children are highly susceptible to the effects of lead.

The entire SCAB is in attainment for the federal and state standards for lead.

Particulate Matter

Particulate matter is the term used for a mixture of solid particles and liquid droplets found in the air. Coarse or respirable particles (all particles less than or equal to 10 micrometers in diameter, or PM_{10}) come from a variety of sources, including windblown dust and grinding operations. Fine particles (less than 2.5 micrometers, or $PM_{2.5}$) often come from fuel combustion, power plants, and diesel buses and trucks. Fine particles can also be formed in the atmosphere through chemical reactions. PM_{10} can accumulate in the respiratory system and aggravate health problems such as asthma. EPA's scientific review concluded that fine particles ($PM_{2.5}$), which penetrate deeply into the lungs, are more likely than coarse particles to contribute to adverse health effects.

The SCAB is designated as a "serious" nonattainment area for federal PM_{10} standards and as a nonattainment area for state PM_{10} standards. In regards to $PM_{2.5}$ attainment status, the SCAB is designated as a nonattainment area by CARB and by the EPA.

Existing Local Air Quality

The SCAQMD maintains ambient air quality monitoring stations throughout the SCAB. The closest ambient air quality monitoring station to the project site is the Perris Valley monitoring station, which measures O_3 and PM_{10}. For CO, NO_2, $PM_{2.5}$, and SO_2, values from the monitoring station closest to the project site that measures that specific pollutant were used in this analysis, as presented in *Table 5.10-4, Ambient Air Quality Data*. The most recent background ambient air quality data from 2006 through 2008 are presented in *Table 5.10-4* below.

Table 5.10-4
Ambient Air Quality Data

Pollutant	Monitoring Station	2006	2007	2008*
O_3				
Maximum 1-hour concentration (ppm)	Perris Valley	0.17	0.139	0.142
# of days of state exceedances (>0.08 ppm)	Perris Valley	76	66	65
Maximum 8-hour average concentration (ppm)	Perris Valley	0.122	0.116	0.115
# of days of state exceedances (>0.070 ppm)	Perris Valley	54	88	94
# of days of fed. exceedances (>0.08 ppm for 2006–07, >0.075 ppm for 2008)	Perris Valley	53	37	77
CO				
Max. Concentration 1 hour (ppm)	Lake Elsinore	1	2	1.1**

SOURCE: South Coast Air Quality Management District (2009)
Metro RC1 = Metropolitan Riverside County 1 (5888 Mission Blvd., Rubidoux)
Metro RC2 = Metropolitan Riverside County 2 (7002 Magnolia Ave., Riverside)
* 2008 data were taken from CARB Air Quality Data Statistics (2009) http://www.arb.ca.gov/adam/welcome.html,
** Data were taken from EPA AirData (2009) http://www.epa.gov/air/data/index.html

As the table above demonstrates, air quality within the project region is in compliance with both CAAQS and NAAQS for CO, NO_2, and SO_2. Federal and state 1-hour and 8-hour O_3 standards were, however, exceeded during each of the last 3 years. The PM_{10} level monitored at the air monitoring stations exceeded the state standard every year of the past 3 years; the federal standard was not exceeded once during this period. The federal standard, however, for $PM_{2.5}$ was exceeded several times during each of the past 3 years.

5.10.3 Significance Criteria

In accordance with Appendix G of the CEQA Guidelines, the proposed project would have a significant impact to air quality if it:

- Conflicts with or obstruction of implementation of the applicable air quality plan.
- Violates any air quality standard or contributes substantially to an existing or projected air quality violation.
- Results in a cumulatively considerable net increase of any criteria pollutant for which the project region is in nonattainment under applicable federal or state ambient air quality standards (including releasing emissions that exceed quantitative thresholds for ozone precursors).
- Exposes sensitive receptors to substantial pollutant concentrations.
- Creates objectionable odors affecting a substantial number of people.

In addition, Appendix G of the CEQA Guidelines indicates that where available, the significance criteria established by the applicable air quality management or pollution control district may be relied upon to determine if the proposed project would have a significant impact on air quality. The SCAQMD CEQA Air Quality Handbook (SCAQMD 1993) sets forth quantitative emission significance thresholds below which a project would not have a significant impact on ambient air quality. Project-related air quality impacts estimated in this environmental analysis would be considered significant if any of the applicable significance thresholds presented in *Table 5.10-5, SCAQMD Air Quality Significance Threshold*s, are exceeded. To evaluate whether a project would result in a substantial contribution to an existing air quality violation of the NAAQS or CAAQS for ozone (see *Table 5.10-2*), which is a nonattainment pollutant, the SCAQMD considers a project to have a significant impact if the project's construction or operational emissions would exceed the VOC or NOx thresholds shown in *Table 5.10-5*. These emission-based thresholds for ozone precursors are intended to serve as a surrogate for an "ozone significance threshold" (i.e., the potential for adverse ozone impacts to occur) because ozone itself is not emitted directly (see discussion of ozone and its sources above) and the effects of an individual project's emissions of ozone precursors (VOC and NOx) on ozone levels in ambient air cannot be determined through air quality models or other quantitative methods.

Table 5.10-5
SCAQMD Air Quality Significance Thresholds

Pollutant	Construction	Operation
Criteria Pollutants Mass Daily Thresholds		
VOC	75 lbs/day	55 lbs/day
NO_x	100 lbs/day	55 lbs/day
CO	550 lbs/day	550 lbs/day
SO_x	150 lbs/day	150 lbs/day
PM_{10}	150 lbs/day	150 lbs/day
$PM_{2.5}$	55 lbs/day	55 lbs/day
Lead [a]	3 lbs/day	3 lbs/day
Toxic Air Contaminants and Odor Thresholds		
(including carcinogens and non-carcinogens)	Maximum Incremental Cancer Risk ≥ 10 in 1 million Hazard Index ≥ 1.0 (project increment)	
Odor	Project creates an odor nuisance pursuant to SCAQMD Rule 402	
Ambient Air Quality for Criteria Pollutants [b]		
NO_2 1-hour average	SCAQMD is in attainment; project is significant if it causes or contributes to an exceedance of the following attainment standards: 0.18 ppm (state)	
NO_2 annual average	0.030 ppm (state)	
CO 1-hour average	SCAQMD is in attainment; project is significant if it causes or contributes to an exceedance of the following attainment standards: 20 ppm (state)	
CO 8-hour average	9.0 ppm (state/federal)	
PM_{10} 24-hour average	10.4 μg/m³ (construction)[c] 2.5 μg/m³ (operation)	
PM_{10} annual arithmetic mean	20.0 μg/m³	
$PM_{2.5}$ 24-hour average	10.4 μg/m³ (construction)[c] 2.5 μg/m³ (operation)	

SOURCE: SCAQMD, 1993
lbs/day = pounds per day
ppm = parts per million
μg/m³ = microgram per cubic meter
≥ = greater than or equal to

[a] The phasing-out of leaded gasoline started in 1976. As gasoline no longer contains lead, the proposed project is not anticipated to result in impacts related to lead; therefore, it is not discussed in this analysis.

[b] Ambient air quality thresholds for criteria pollutants based on SCAQMD Rule 1303, Table A-2 unless otherwise stated.

[c] Ambient air quality threshold based on SCAQMD Rule 403.

The SCAQMD CEQA Air Quality Handbook also sets forth additional indicators of potential air quality impacts which should be used as screening criteria indicating the need for further analysis. The additional indicators are as follows:

- Project could interfere with the attainment of the federal or state ambient air quality standards by either violating or contributing to an existing or projected air quality violation.
- Project could result in population increases within the regional statistical area which would be in excess of that projected in the AQMP and in other than planned locations for the project's build-out year.
- Project would have the potential to create or be subjected to an objectionable odor over 10 dilutions to thresholds (D/T) that could impact sensitive receptors.
- Project would have hazardous materials on site and could result in an accidental release of air toxic emissions or acutely hazardous materials posing a threat to public health and safety.
- Project could emit an air toxic contaminant regulated by District rules or that is on a federal or state air toxic list.
- Project could involve burning of hazardous, medical, or municipal waste as waste-to-energy facility.
- Project could be occupied by sensitive receptors within a quarter mile of an existing facility that emits air toxics identified in District Rule 1401 or near CO hot spots.
- Project could emit carcinogenic or toxic air contaminants that individually or cumulatively exceed the maximum individual cancer risk of 10 in 1 million.

In addition to the above listed emission-based thresholds, the SCAQMD also recommends the evaluation of localized air quality impacts to sensitive receptors in the immediate vicinity of the project as a result of construction activities. For project sites greater than 5 acres, potential impacts on local sensitive receptors are determined using an air quality dispersion model. Those impacts are then compared to the localized significance thresholds (LSTs). The LSTs for NO_2 and CO represent the allowable increase in concentrations above background levels in the vicinity of a project that would not cause or contribute to an exceedance of the relevant ambient air quality standards. The threshold for PM_{10} represents compliance with Rule 403 (Fugitive Dust). The significance threshold for $PM_{2.5}$ is intended to ensure that construction emissions do not contribute substantially to existing exceedances of the $PM_{2.5}$ ambient air quality standards. The LSTs for NO_2 and CO were derived from the ambient air quality data for the 3 previous years as shown in *Table 5.10-3*. For construction, the LSTs for PM_{10} and $PM_{2.5}$ are both 10.4 $\mu g/m^3$ (SCAQMD 2008). The LSTs applicable to construction of the proposed project, along with the relevant ambient air quality standards, are shown in *Table 5.10-6, Localized Significance Thresholds.*

Table 5.10-6
Localized Significance Thresholds

Pollutant	Averaging Period	CAAQS/NAAQS		Peak Conc. in ppm	LST Criteria*	
		µg/m³	ppm			
Nitrogen Dioxide (NO2)	1 hour	339	0.18	0.07	207	0.11
Carbon Monoxide (CO)	1 hour	23,000	20	2	20,598	18
Carbon Monoxide (CO)	8 hours	10,000	9.0	1.4	8,697	7.6
Respirable Particulate Matter (PM10)	24 hours	50	—	NA	10.4	—
Fine Particulate Matter (PM2.5)**	24 hours	35	—	NA	10.4	—

SOURCE: SCAQMD 2008.

* LST Criteria for NO2 and CO are the differences between CAAQS and the Peak Concentration.

** California has not adopted a 24-hour AAQS for $PM_{2.5}$. The 24-hour $PM_{2.5}$ AAQS shown is the national standard.

To date, no local or state air quality agency has adopted significance criteria for GHG emissions for residential and commercial projects. Nonetheless, this Draft EIR provides a discussion of the impacts of the project with respect to global climate change in the absence of an established significance threshold. To assess the impact of the proposed project with respect to global climate change, the potential contribution of the project to this cumulative impact is evaluated under the following criterion:

- The project could impede or conflict with the emissions reduction targets and strategies prescribed in or developed to implement AB 32.

This analysis conforms closely to the methodologies recommended in the California Air Pollution Control Officers Association *CEQA and Climate Change* discussion (CAPCOA 2008). Calculations of carbon dioxide, methane, and nitrous oxide associated with the proposed project are provided for full disclosure of the magnitude of potential impacts. While a project may result in emission of GHGs, the significance of the impacts of a single project on the global climate cannot be quantified. The full disclosure of project GHG emissions is intended to provide information, which may be useful for regional agencies in the context of eventually developing regional or statewide emission projections.

5.10.4 Impacts

This section evaluates the air quality impacts associated with 1,016 single-family detached residential dwelling units, a high school with 2,000 students, 45.9 acres of park use, 281,570 square feet of general commercial/retail use, and 309,320 square feet of office type uses (general office and government complex such as a post office). If the 2,000-student high school site is not chosen by the School District, an additional 322 single-family detached residential dwelling units will be developed alternatively in Phase III. For purposes of air quality impact analysis, based on

the Institute of Transportation Engineers traffic rates (please refer to Traffic section), the development of the 2,000-student high school (as opposed to the alternative development of 322 residential units) would be the reasonable worst-case project, and is therefore, evaluated herein.

Would the project conflict with or obstruction of implementation of the applicable air quality plan?

While striving to achieve the NAAQS for ozone and $PM_{2.5}$ through a variety of air quality control measures, the 2007 AQMP also accommodates planned growth in the SCAB. Projects are considered to be consistent with, and would not conflict with or obstruct implementation of, the AQMP if the growth in socioeconomic factors (e.g., population, employment) are consistent with the underlying regional plans used to develop the AQMP. As indicated in Chapter 3 of the 2007 AQMP, demographic growth forecasts for various socioeconomic categories, developed by SCAG for their interim 2007 Regional Transportation Plan (RTP), were used in the modified 2004 RTP to estimate future emissions in the 2007 AQMP (SCAQMD 2007). Key growth forecasts for the City of San Jacinto from the modified 2004 RTP (SCAG 2004) include:

- Population: 31,256 (2010), 40,025 (2025), 42,738 (2030)
- Employment: 8,587 (2010), 10,834 (2025), 11,620 (2030).

According to the California Department of Finance, the population of the City of San Jacinto as of January 1, 2009, was 36,477 (Department of Finance 2009). The estimated population of the proposed project, assuming that 322 single-family residences are built instead of the potential high school is 4,054, which would be achieved by 2023 according to the prescribed phasing of the project. When added to the current population, the total population (40,531) would exceed the forecasted population of the City of San Jacinto in 2025 but not 2030. However, the population growth projections for the neighboring City of Hemet are substantially higher than the current population. The SCAG RTP 2010 and 2025 population projections for the City of Hemet are 105,100 and 154,392, respectively, whereas the current Department of Finance 2009 population is 74,361 (Department of Finance 2009), more than 30,000 persons less than the 2010 projection. (This shift between the two cities is reflected in the population forecasts for the 2008 RTP, which shows higher growth for the City of San Jacinto and lower growth for the City of Hemet [SCAG 2008]). Accordingly, the proposed project would be accommodated in the subregional population forecasts used to prepare the 2007 AQMP.

The most recent employment estimate (May 2009) from the California Employment Development Department indicates 10,000 employees in the City of San Jacinto (California Employment Development Department 2009). The proposed project would create an estimated 675 jobs at full buildout in 2033. Thus, the total employment (10,675) would be within the

SCAG modified 2004 RTP forecast for 2030. Accordingly, the proposed project's employment would be accommodated in the forecasts used to prepare the 2007 AQMP.

As described in *Section 3.0, Project Description,* implementation of the proposed project would require a General Plan Amendment. The current General Plan includes residential, open space, and commercial land use designations for the project site. *Table 5.1-1, General Plan and Specific Plan Comparison,* in *Section 5.1 Land, Use, Planning, and Zoning,* compares the General Plan and Specific Plan levels of development. As shown in this table, the Specific Plan would provide for up to 1,329 residential units (assuming the potential high school is not built) and 49 acres of commercial and mixed use development. These values are less than the 3,077 residential units and 54.4 acres of commercial development that would be allowed under the current General Plan land used designations for the site. As indicated in *Section 5.1,* the Specific Plan's potential inconsistency with the existing General Plan Land Use Map is considered less than significant from a Land Use Plan Map perspective. *Section 5.1* also provides a detailed analysis of the Specific Plan's consistency with General Plan goals and policies.

Based on the preceding assessment, the proposed project would not conflict with or obstruct implementation of the AQMP, and this impact would be less than significant.

Would the project result in a cumulatively considerable net increase of any criteria pollutant for which the project region is in nonattainment under applicable federal or state ambient air quality standards (including releasing emissions that exceed quantitative thresholds for ozone precursors).

Construction Activity Impacts

Construction activities, including soil disturbance dust emissions and combustion pollutants from on-site construction equipment and from off-site trucks hauling dirt, cement or building materials would create a temporary addition of pollutants to the local airshed. These emissions are variable in time and space and differ considerably among various construction projects. Such emission levels can, therefore, only be approximately estimated with a corresponding uncertainty in precise ambient air quality impacts.

Emissions from the construction phase of the project were estimated through the use of emission factors from the URBEMIS 2007, Version 9.2.4, land use and air emissions model and the SCAQMD's CEQA Air Quality Handbook (SCAQMD 1993).

Construction phasing and other URBEMIS modeling assumptions are based on the project phasing in the project's Traffic Impact Study (refer to *Section 5.9, Transportation, Circulation, and Access*) and the project description provided in the Specific Plan. For purposes of this assessment, the following assumptions were made regarding the project phases and construction

subsphases. Mass grading for the entire site would start in December 2011 and would be completed 7 months after. The grading plans anticipate that cut and fill will be balanced; no export or import of soil is planned. Phase I would be completed in December 2015. Fine grading for Phase II would start immediately after the completion of Phase I in January 2016. Phase II would be completed in December 2017. Phase III would commence immediately after the completion of Phase II in December 2017. Phase III would include the construction of single-family residences and a high school. In July 2018, six months into the development phase, construction of the high school would start. Phase III, including the high school, would be completed in December 2023. Construction of the remaining nonresidential land uses in Phase IV would start in January 2024 and would be completed by December 2033.

Additional details of the construction schedule are included in *Appendix I.*

The project would involve multiple construction subphases: 1) mass grading, 2) fine site grading of individual phases, 3) utilities/infrastructure (trenching), 4) building construction, 5) paving, and 6) architectural coating. Phases I, II, III, and IV would involve separate construction subphases with the exception of mass grading, which will cover the entire project site and occur during Phase I only. The proposed project would commence in 2011 and would be completed by 2033, for a total construction duration of 22 years. Within the analysis, it was generally assumed that heavy construction equipment would be operating at the site for approximately 8 hours per day, six days per week (26 days a month), during project construction.

URBEMIS 2007 model defaults were utilized where detailed project data is unknown at this time (refer to *Appendix I*). For example, the specific construction equipment and specifications may change over time and cannot be identified with certainty during the planning phase. To account for dust control measures in the calculations, it was assumed that the active sites would be watered at least three times daily, resulting in a approximately 61% reduction, to comply with Rule 403. *Table 5.10-7, Heavy Construction Equipment,* presents the heavy construction equipment assumptions for each construction stage, as applied in the model. The assumptions identified above and the number of equipment units presented in the table below represent a reasonably conservative estimate of construction activity.

SOURCE: URBEMIS 2007 V 9.2.4 Phase Assumptions (see *Appendix I*).

In addition to the heavy construction equipment identified above, construction material delivery truck and worker trips and architectural coatings were calculated for all relevant construction phases based on URBEMIS 2007 defaults. *Table 5.10-8, Estimated Maximum Daily Construction Emissions*, provides a summary of the emission estimates for the construction phase of the proposed project. Refer to *Appendix I* for detailed emission calculations.

SOURCE: URBEMIS 2007 Version 9.2.4 Appendix I for calculations.
NOTES: These estimates reflect control of fugitive dust required by Rule 403. Emissions in bold represent the maximum pollutant emissions that would occur over any day during the construction for the specific year and that would exceed the significance thresholds

Ground disturbances and equipment operation during construction activities would produce potentially significant short-term PM_{10} and $PM_{2.5}$ emissions. Implementation of the proposed project would generate construction-related air pollutant emissions from two general activity categories, entrained dust and vehicle emissions. Entrained dust results from the exposure of earth surfaces to wind from the direct disturbance and movement of soil, resulting in PM_{10} and $PM_{2.5}$ emissions. Vehicle exhaust results from internal combustion engines used by construction equipment and vehicle which results in emissions of NO_x, VOCs, CO, PM_{10}, and $PM_{2.5}$.

As shown in the preceding table, maximum construction-generated PM_{10} emissions of 36.58 pounds per day would be below the SCAQMD's quantitative significance threshold of 150 pounds per day. $PM_{2.5}$ maximum daily emissions of 8.48 lbs/day would also be below the established threshold of 55 pounds per day. Although such fugitive dust would be short term and would only last during the duration of grading activity, such PM_{10} and $PM_{2.5}$ emissions could be considered problematic since they could cause a public nuisance or further exacerbate the existing PM_{10} nonattainment situation in the SCAB. During construction, the project would be subject to SCAQMD Rule 403 (Fugitive Dust), which sets forth general and specific requirements for all construction sites (as well as other fugitive dust sources) in the SCAQMD, but does not require a permit for construction activities. The general requirement prohibits a person from causing or allowing emissions of fugitive dust from construction (or other fugitive dust source) such that the presence of such dust remains visible in the atmosphere beyond the property line of the emissions source. SCAQMD Rule 403 also prohibits a construction site from causing an incremental PM_{10} concentration impact at the property line of more than 50 micrograms per cubic meter as determined through PM_{10} high-volume sampling, but the concentration standard and associated PM_{10} sampling do not apply if specific measures identified in the rule are implemented and appropriately documented. In order to reduce potential PM_{10} impacts and fugitive dust emissions, mitigation is recommended (see *Section 5.10.5, Mitigation*

Measures, Mitigation Measure 5.10-a). Without mitigation, however, air quality impacts related to anticipated PM_{10} emission levels during construction would be considered less than significant.

The application of architectural coatings (exterior/interior paint and other finishings) would produce VOC emissions that would exceed the SCAQMD's established quantitative significance threshold. As indicated above in *Table 5.10-8*, maximum construction-generated VOC emissions in 2019 would exceed the 75 lbs/day significance threshold. In order to reduce these potential impacts, mitigation is provided (see *Section 5.10.5, Mitigation Measures*, Mitigation Measure 5.10-c). Although mitigation is provided, these impacts would not be reduced to a level below significance; therefore, the construction phase of the project would result in significant, unmitigable air quality impacts due to anticipated VOC emission levels.

Operational Impacts

Operations of the project would produce VOC, NO_x, CO, SO_x, PM_{10} and $PM_{2.5}$ emissions from all combined proposed residential and nonresidential project land uses, including vehicular traffic, space heating and cooling, water heating, and consumer products.

Specifically, the proposed project would impact air quality through the vehicular traffic generated by project residents, visitors, customers and employees. According to the project's traffic analysis (see *Section 5.9, Transportation, Circulation, and Access*), total project-generated daily traffic is estimated to be 27,166 trip-ends per day. The URBEMIS 2007 model was utilized to estimate daily emissions from proposed vehicular sources (refer to *Appendix I*, which includes the data and assumptions used to generate emissions information summarized within this section for both the summer and winter seasons). URBEMIS 2007 default data, including temperature, trip characteristics, variable start information, emission factors, and trip distances, were conservatively used for the model inputs. Project-related traffic (identified above) was assumed to be comprised of a mixture of vehicles in accordance with the model outputs for traffic. This assumption includes light-duty autos and light-duty trucks (i.e., small trucks, SUVs, and vans) as well as medium- and heavy-duty vehicles that may be traveling within the project area to make deliveries or as business customers with larger vehicles. Emission factors representing the vehicle mix and emissions for the year 2017 and 2020 were used to estimate emissions. The year 2017 would be an intermediate year of development, and 2020 was assumed to be the year of full occupancy/operation. It is expected that project emissions would decrease on an annual basis from 2020 onward due to phase-out of higher polluting vehicles and implementation of more stringent emission standards.

In addition to estimating mobile source emissions, the URBEMIS 2007 model was also used to estimate emissions from the project area sources, which include natural gas appliances, natural-

gas burning fireplaces, gas-powered landscape maintenance equipment, architectural coatings, and consumer products. It should be noted that as specific operational characteristics of the proposed business park and retail uses are presently unknown, associated process activity emissions for any specific uses cannot be estimated at this time. However, if these emissions were substantial, they may require further CEQA analysis and would fall under the jurisdiction of the SCAQMD air permit process which would require the application of standard mitigation measures and permit conditions and/or emission offsets to ensure that any proposed stationary emissions remain less than significant. The present estimation of proposed operational emissions is based upon typical business park and commercial uses for this type of project, and the analysis is considered a reliable estimate of the project's likely emissions.

Table 5.10-9, Summary of Estimated Phase I + Phase II + Phase III Operational Air Pollutant Emissions, presents the maximum daily emissions associated with partial build-out of the proposed project during the year 2023. Details of the emission calculations are provided in *Appendix I*.

Source: URBEMIS 2007 V 9.2.4
The URBEMIS2007 year options for operational emissions modeling are in five-year increments, starting in 2020. As such, the year 2020 was utilized in the model to represent year 2023, which is a conservative approach.

As shown in *Table 5.10-9*, operation of Phase I, Phase II, and Phase III of the proposed project would exceed SCAQMD established thresholds for VOC, NO_x, CO, and PM_{10}.

The peak daily emissions predicted for the both the summer and winter season in the project's full buildout of operation (2033) are summarized in *Table 5.10-10, Summary of Estimated Full*

Buildout Operational Air Pollutant Emissions, along with a comparison with the SCAQMD's significance criteria. Details of the emission calculations are provided in *Appendix I*.

SOURCE: URBEMIS 2007 V 9.2.4
The URBEMIS2007 year options for operational emissions modeling are in five-year increments, starting in 2020. As such, the year 2030 was utilized in the model to represent year 2033, which is a conservative approach.

As shown in the preceding table, the projected operational emissions from both area source and vehicular emissions are substantially above the SCAQMD significance criteria for all pollutants except SO_x. This would represent a significant impact with regard to operation of the project, and therefore, mitigation would be required (see *Section 5.10.5, Mitigation Measures*, Mitigation Measure 5.10-d). Even with implementation of Mitigation Measure 5.10-d, long-term operational air quality impacts would be considered significant and unmitigable.

Mobile source impacts occur basically on two scales of motion. Regionally, project-related travel will add to regional trip generation and increase the vehicle miles traveled (VMT) within the local airshed. Locally, project traffic will be added to the San Jacinto roadway system near the project area. If such traffic occurs during periods of poor atmospheric ventilation, is comprised of a large number of vehicles "cold-started" and operating at pollution-inefficient speeds, and is operating on roadways already crowded with non-project traffic, there is a potential for the formation of micro-scale air pollution CO "hot spots" in the area immediately around points of congested traffic. Because of continued improvement in vehicular emissions at a rate faster than the rate of vehicle growth and/or congestion, regional air pollution "hot spot" potential is steadily decreasing.

Projects involving adverse traffic impacts may result in the formation of CO hot spots. To verify that the project would not cause or contribute to a violation of the CO standard, a screening evaluation of the potential for CO hot spots was conducted. The project's Traffic Impact Study (refer to *Section 5.9, Transportation, Circulation, and Access*) evaluated whether or not there would be a decrease in the level of service at the intersections affected by the project. The potential for CO hot spots was evaluated based on the results of the traffic study. The Caltrans ITS Transportation Project-Level Carbon Monoxide Protocol (Caltrans 1998) was followed.

In accordance with the Protocol, CO hot spots are typically evaluated when: 1) the level of service (LOS) of an intersection or roadway decreases to a LOS E or worse; 2) signalization and/or channelization is added to an intersection; and 3) sensitive receptors such as residences, commercial developments, schools, and hospitals are located in the vicinity of the affected intersection or roadway segment.

The project traffic study evaluated 16 intersections in the project vicinity to evaluate project build-out/General Plan build-out LOS (2033). The traffic study assumed the implementation of a number of traffic improvements which reduce and/ or maintain traffic levels of services at 11 out of the 16 identified study intersections at LOS D or above under the General Plan build-out scenario (refer to *Section 5.9, Transportation, Circulation, and Access* for specific data).

Although the remaining 5 intersections would operate at unacceptable level of service under the project build-out/General Plan build-out condition, the County of Riverside and Riverside County Transportation Commission (RCTC) have yet to define the future design configurations for these regional intersections under General Plan Buildout conditions. Although it may be reasonable to assume that RCTC will complete the design and implementation of these regional interchange improvements prior to project/General Plan build-out, which the applicant will fund in part through payment of appropriate mitigation fees [Western Riverside County Transportation Uniform Mitigation Fee (TUMF) and City of San Jacinto Traffic Fees], and that these regional improvements would operate at an LOS D or above; until such time as these improvements are planned and funded, CO hotspot impacts must be assumed to occur at these intersections. This would represent a significant impact with regard to cumulative operation of the project and therefore, mitigation would be required (see *Section 5.10.5, Mitigation Measures,* Mitigation Measure 5.10-e). Even with implementation of Mitigation Measure 5.10-e, long-term operational air quality impacts would be considered significant and unmitigable.

Health Impacts of Criteria Air Pollutants Emissions

The construction of the proposed project would result in VOC emissions that exceed the SCAQMD mass-emission thresholds; all other criteria pollutants were found to be less than significant. Specific VOCs may be toxic air contaminants; however, the specific VOCs

associated with project construction are unknown. Some VOC would be associated with motor vehicles and construction equipment, while others are associated with architectural coatings, the emissions of which would result in the exceedances of the SCAQMD threshold as shown in *Table 5.10-8*. Generally, the VOCs in architectural coatings are of relatively low toxicity. In addition, VOCs are a precursor to ozone, for which the SCAB is designated as nonattainment with respect to the NAAQS and CAAQS. Thus, existing ozone levels in the SCAB are at unhealthy levels during certain periods. The health effects associated with ozone, as discussed in *Section 5.10.2*, are generally associated with reduced lung function. The contribution of VOCs to regional ambient ozone concentrations is the result of complex photochemistry. The increase in ozone concentrations in the SCAB due to ozone precursor emissions tend to be found downwind from the source location to allow time for the photochemical reactions to occur. However, the potential for exacerbating excessive ozone concentrations also would depend on the time of year that the VOC emissions would occur because exceedances of the ozone AAQS tend to occur between April and October when solar radiation is highest. The effect of a single project's emissions of ozone precursor is speculative due to the lack of quantitative methods to assess this impact. Nonetheless, the VOC emissions associated with project construction could contribute to regional ozone concentrations and the associated health impacts.

According to the LST analysis, the construction of the proposed project could contribute substantially to exceedances of the NAAQS and CAAQS for PM_{10} and $PM_{2.5}$. As described in *Section 5.10.2*, PM_{10} and $PM_{2.5}$ can accumulate in the respiratory system and aggravate health problems such as asthma. For the proposed project, the possibility of impacting nearby receptors depends on the presence of receptors at neighboring parcels and their proximity to active construction areas. Currently, the project site is surrounded by agricultural uses rather than existing neighborhoods. An existing residence is located approximately 500 feet southeast of the southeast corner of the project site. Furthermore, the primary source of PM_{10} and $PM_{2.5}$ emissions would be mass grading of the project site, followed by fine grading of the residential and commercial/mixed-use phases. These operations are relatively short-term and would be well controlled to comply with SCAQMD Rule 403 (e.g., no visible dust may leave the construction site). Accordingly, it is expect that any potential increases in health impacts associated with PM_{10} and $PM_{2.5}$ would be minor and temporary.

During operation of the proposed project, the emissions of VOC, NO_x, CO, PM_{10}, and $PM_{2.5}$ would exceed the SCAQMD mass-emission thresholds. The VOC and NO_x emissions, as described above, would contribute to regional ozone concentrations and the associated health effects. In addition to ozone, NO_x contributes to potential exceedances of the NAAQS and CAAQS for NO_2. As shown in *Table 5.10-4*, the existing NO_2 concentrations are well below the NAAQS and CAAQS. Thus, it is not expected the project's NO_x emissions would result in exceedances of the NO_2 standards or contribute to the associated health effects. CO tends to be a localized impact associated with congested intersections. The associated CO "hot spots" were

discussed previously as a significant and unavoidable impact after mitigation. Thus, the project's CO emissions may contribute to the health effects associated with this pollutant, which include impairments to central nervous system functions. The PM_{10} and $PM_{2.5}$ emissions during operation would result primarily from fugitive road dust and, to a lesser extent, motor vehicle exhaust. Thus, the emissions would be dispersed throughout the project area and not confined to specific locations that would result in localized impacts to receptors. The PM_{10} and $PM_{2.5}$ would contribute to the regional exceedances of the NAAQS and CAAQS and the associated health effects for these pollutants.

Would the project violate any air quality standard or contributes substantially to an existing or projected air quality violation?

As indicated in the discussion of the thresholds of significance, the SCAQMD also recommends the evaluation of localized NO_2, CO, PM_{10}, and $PM_{2.5}$ impacts as a result of construction activities to sensitive receptors in the immediate vicinity of the project site. The impacts were analysis using methods consistent with those in the SCAQMD's *Final Localized Significance Threshold Methodology* (SCAQMD 2008). The Industrial Source Complex – Short Term, Version 3 (ISCST3) air quality dispersion model was used for the analysis. ISCST3 is approved for use by the SCAQMD for the purposes of performing an LST analysis. Details of the LST analysis are described in *Appendix I*.

Table 5.10-11, LST Modeling Results, shows the maximum NO_2, CO, PM_{10}, and $PM_{2.5}$ concentrations associated with the proposed project at sensitive receptors in the vicinity of the project site. The values shown in these tables are the maximum results associated with the construction phase and activity producing the highest impacts.

Table 5.10-11
LST Modeling Results

Pollutant	Averaging Period	Modeling Results		LST Criteria		Exceeds Threshold?
		µg/m³	ppm	µg/m³	ppm	
Nitrogen Dioxide (NO_2)	1 hour	12.2	0.01	244	0.13	NO
Carbon Monoxide (CO)	1 hour	115	0.10	17,165	15	NO
Carbon Monoxide (CO)	8 hours	48	0.04	6,065	5.3	NO
Respirable Particulate Matter (PM_{10})	24 hours	70.4	NA	10.4	NA	**YES**
Fine Particulate Matter ($PM_{2.5}$)	24 hours	15.7	NA	10.4	NA	**YES**

As shown in *Table 5.10-11*, the project impacts on NO_2 and CO concentrations would not cause or contribute to exceedances of the CAAQS. The maximum 24-hour PM_{10} and $PM_{2.5}$ concentrations are anticipated to exceed the LST at the maximally impacted sensitive receptor in

the vicinity of the project site. Thus, construction of the proposed project would result in significant air quality impacts during the construction phase.

Would the project create objectionable odors affecting a substantial number of people?

Odors are a form of air pollution that is most obvious to the general public. Odors can present significant problems for both the source and surrounding community. Although offensive odors seldom cause physical harm, they can be annoying and cause concern. During the construction period, the potential odors associated with the proposed project would result from the application of asphalt, from diesel and gas fumes, and from the application of paint. Due to the temporary nature of construction and the relatively sparse population surrounding the project site (i.e., mostly agricultural fields), temporary odors associated with project construction would be considered less than significant.

During the operational phase of the proposed project, anticipated odors would be generated from cooking facilities and landscape/building maintenance. In general, these odors are not considered to create a significant nuisance and it is not likely that these odors would cause a significant impact to surrounding receptors. Nevertheless, if specific businesses within the proposed commercial component of the project are identified and specific permits are requested for uses that could cause a significant impact, the City of San Jacinto may further evaluate odor emissions from such uses to determine if additional environmental review is warranted at that time. In addition to these potential odor sources, the proposed project would incorporate a detention basin that will collect the runoff that emanates from offsite and onsite areas and will serve as a regional water quality facility for the project. Proper maintenance of the detention basin including periodic cleaning and maintaining aerobic conditions should alleviate the potential for the collected water to generate objectionable odors. At this time, however, long-term operational impacts associated with project-generated odors would be considered less than significant.

The project site is bordered by undeveloped agricultural land to the north (and future westward extension of Ramona Boulevard), Sanderson Avenue to the east, Odell Avenue to the west, and undeveloped agricultural land and a municipal wastewater treatment plant to the south (see *Figure 3.3, Project Location Map*). Land uses in the project area consist of agricultural operations including sod farms, dry farming, animal grazing pastures and dairies. Although several parcels within the project vicinity are in the process of being developed with residential subdivisions and/or commercial centers, project residents, employees, and/or customers may be subjected to noticeable odors associated with standard agricultural operations (fertilizers, pesticides, etc.) and/or odors associated with the wastewater treatment plant (WWTP) operations to the south. The odors associated with agriculture are often characterized as having a heavy, pungent nitrogen smell, while the odors associated with the WWTP can at times (particularly in hotter conditions) smell rotten and sulfuric in character. Odors would likely be most pronounced

on days when hot temperatures are experienced and/or gusts of winds occur. Given the proximity of the project to off-site odor sources, the project could result in odor nuisance complaints. As a part of the proposed project specific plan, the applicant has agreed to incorporate setbacks, fencing, and vegetative screening to protect and/or screen sensitive project receptors. Potential off-site odor impacts would, therefore, be considered less than significant.

Would the project expose sensitive receptors to substantial pollutant concentrations?

Toxic air contaminants (TACs) are defined as substances that may cause or contribute to an increase in deaths or in serious illness, or which may pose a present or potential hazard to human health. Although not anticipated at this time, if a business/commercial use is subsequently proposed that would involve potential TACs that require air permits, such permits would be subject to SCAQMD health risk assessment and public notification requirements. The SCAQMD permit requires the application of appropriate safeguards to ensure the public safety. If specific permits are requested for uses that could create TACs, the City of San Jacinto may further evaluate the project to determine if additional environmental review is warranted at that time. At this time, however, long-term operational impacts associated with toxic air contaminants are considered less than significant.

CARB has published the *Air Quality and Land Use Handbook: A Community Health Perspective* (CARB 2005), which identifies certain types of facilities or sources that may emit substantial quantities of TACs and therefore could conflict with sensitive land uses, such as "schools and schoolyards, parks and playgrounds, daycare centers, nursing homes, hospitals, and residential communities." The *Air Quality and Land Use Handbook* is a guide for siting of new sensitive land uses, but it does not mandate specific separation distances to avoid potential health impacts. The enumerated facilities or sources include:

- High traffic freeways and roads
- Distribution centers
- Rail yards
- Ports
- Refineries
- Chrome plating facilities
- Dry cleaners
- Large gas dispensing facilities

CARB recommends that sensitive receptors not be located downwind or in proximity to such sources to avoid potential health hazards.

With the possible exception of dry cleaners, the proposed project would not include these types of TAC sources on site. (New dry cleaners in the SCAQMD are prohibited from using perchloroethylene, a TAC; thus, siting of a dry cleaner within the proposed project would not result in TAC emissions). Moreover, the proposed project's residential uses, parks, or the potential high school would not be located in proximity to any of these listed sources off site. Accordingly, the proposed project would not generate substantial TAC emissions that would conflict with surrounding sensitive receptors nor expose the project's inhabitants to TAC emissions from these sources.

Would the project could impede or conflict with the emissions reduction targets and strategies prescribed in or developed to implement AB 32?

Quantification of GHG Emissions

In January 2008, the California Air Pollution Control Officers Association (CAPCOA) published *CEQA and Climate Change: Evaluating and Addressing Greenhouse Gas Emissions from Projects Subject to the California Environmental Quality Act*. This white paper is "intended as a resource, not a guidance document. It is not intended, and should not be interpreted, to dictate the manner in which an air district or lead agency chooses to address greenhouse gas emissions in the context of its review of projects under CEQA" (CAPCOA 2008). This document describes analytical methodologies for estimating direct (mobile and area sources) and indirect (electrical and water/wastewater utilities) GHG emissions associated with a development project. For the most part, the calculation methods described below are consistent with this guidance as well as the OPR technical advisory (OPR 2008).

Construction GHG Emissions

Emissions from Construction Equipment and Vehicles

Construction of the proposed project would result in GHG emissions, which are primarily associated with use of off-road construction equipment and vehicles and on-road construction and worker vehicles. The URBEMIS 2007 model was used to calculate the annual CO_2 emissions based on the construction scenario described in *Section 5.10.4*. The model results were adjusted to estimate methane (CH_4) and nitrous oxide (N_2O) emissions in addition to CO_2. The CO_2 emissions from off-road equipment and vehicles and delivery trucks, which are assumed by URBEMIS 2007 to be diesel fueled, were adjusted by a factor derived from the relative CO_2, CH_4, and N_2O for diesel fuel as reported in the California Climate Action Registry's (CCAR) *General Reporting Protocol* (CCAR 2009) for transportation fuels and the GWP for each GHG. The CO_2 emissions associated with construction worker trips were multiplied by a factor based on the assumption that CO_2 represents 95% of the CO_2E emissions associated with passenger vehicles (EPA 2005). The results were then converted from annual tons per year to metric tons

per year. As shown in *Table 5.10-12, Estimated Annual Construction Emissions of Greenhouse Gases*, the maximum GHG emissions during construction would range from 29 metric tons of emissions per year (expressed as CO_2 equivalent) to 1,771 metric tons per years, peaking in 2014 and 2015. Additional detail regarding these calculations is found in *Appendix I*.

Table 5.10-12
Estimated Annual Construction Emissions of Greenhouse Gases

Construction Year	Metric Tons CO_2E/Year
2011	29
2012	335
2013	1,644
2014	1,771
2015	1,771
2016	859
2017	1,406
2018	953
2019	1,707
2020	1,208
2021	1,204
2022	1,204
2023	1,201
2024	483
2025	647
2026	647
2027	647
2028	647
2029	693
2030	693
2031	693
2032	695
2033	693

Emissions from Release of Methane from Disturbed Soil During Construction

The project site included a former 20-acre cattle operation. If manure from this operation remained on the site and were buried where it could undergo anaerobic decomposition and generate methane (a GHG), methane could be released to the atmosphere during subsurface operations such as excavation. Surface or near surface deposits of manure would undergo aerobic decomposition, which does not generate methane. However, according to the Phase I environmental site assessment (*Appendix L*), the manure was removed from the site for use as fertilizer. Mitigation Measure 5.13-a in *Section 5.13, Hazards*, addresses the potential for

methane releases from the former cattle operation. Methane investigations would take place and in the event that methane is detected in this area, installation of mitigation mechanisms to collect methane would occur in accordance with the most recent Riverside County Department of Environmental Health's preliminary methane investigation protocols.

Operational GHG Emissions

Development of the proposed project would result in the generation of GHGs, primarily CO_2. The project includes features that would reduce the generation of GHG relative to a project developed without these features. The latter scenario is described as "business-as-usual" in the following discussion. The following sections discuss the calculations of GHG emissions resulting from the primary sources of GHGs associated with the operation of the proposed project at full buildout in 2033.

Emissions from Motor Vehicles

Annual CO_2 emissions from motor vehicle trips for full project buildout in 2033 were quantified using the URBEMIS 2007 model. As described above for construction worker vehicles, CH_4 and N_2O emissions were accounted for by multiplying the URBEMIS 2007 CO_2 emissions by a factor based on the assumption that CO_2 represents 95% of the CO_2E emissions associated with passenger vehicles (EPA 2005). The business-as-usual scenario assumes that the project would be developed with single-family residential only. The commercial and mixed-use development was assumed to be developed at a different, noncontiguous location. Accordingly, the adjustment of the trip generation for "internal capture" (also referred to as "double counting") would not occur. To generate the business-as-usual emissions associated with motor vehicles, the URBEMIS 2007 model was run without an adjustment for double counting. The estimated GHG emissions from motor vehicles under the business-as-usual scenario are shown in *Table 5.10-13, Estimated Business-As-Usual Operational Emissions of Greenhouse Gases*. The estimated GHG emissions from motor vehicles under the proposed project scenario are shown in *Table 5.10-14, Estimated Proposed Project Operational Emissions of Greenhouse Gases* Additional details regarding these calculations are found in *Appendix I.*

Emissions from Natural Gas Combustion and Landscape Maintenance

Annual CO_2 emissions from natural gas combustion for space and water heating and gas fireplaces (new wood-burning devices are prohibited in the SCAB) were estimated using URBEMIS 2007. The CO_2 emissions were adjusted by a factor derived from the relative CO_2, CH_4, and N_2O for natural gas as reported in the CCAR's *General Reporting Protocol* (CCAR 2009) for stationary combustion fuels and their GWPs. Implementation of the Specific Plan's Energy Efficiency Guidelines would likely result in a reduction in the GHG emissions from natural gas usage. However, those emission reductions cannot be quantified because the

Guidelines do not provide sufficient detail to compute the reduction in natural gas usage. The estimated GHG emissions from natural gas combustion are shown in *Tables 5.10-13* and *5.10-14* under the business-as-usual and proposed project scenarios, respectively. Additional details regarding these calculations are found in *Appendix I.*

URBEMIS 2007 estimates the CO_2 emissions associated with use of landscape maintenance equipment. The contribution from this source category is very small; thus, it was assumed that the CO_2 emissions account for all of the GHG emissions.

Emissions from Electricity Use

Annual electricity use was based upon the SCAQMD's estimated generation rates for the land uses of the proposed project (SCAQMD 1993). Development of the proposed project at buildout would consume approximately 16,323,400 kilowatt-hours per year (see *Appendix I* for calculations). The generation of electricity through combustion of fossil fuels typically results in emissions of CO_2 and to a smaller extent CH_4 and N_2O. Annual electricity emissions were estimated using the reported CO_2 emissions per kilowatt-hour for Southern California Edison, which would provide electricity for the project (CCAR 2009).[5] The contributions of CH_4 and N_2O for powerplants in California were obtained from the CCAR's *General Reporting Protocol*, which were adjusted for their GWPs. Implementation of the Specific Plan's Energy Efficiency Guidelines would likely result in a reduction in the GHG emissions associated with electrical use and generation. However, those emission reductions cannot be quantified because the Guidelines do not provide sufficient detail to compute the reduction in electrical usage. *Tables 5.10-13* and *5.10-14* show the estimated emissions of GHGs associated with electrical use under the business-as-usual and proposed project scenarios, respectively. Additional details regarding these calculations are found in *Appendix I.*

Emissions from Water Supply and Wastewater Treatment

Water supplied to the proposed project is a large user of electricity. Accordingly, the supply, conveyance, treatment, and distribution of water would indirectly result in GHG emissions. The GHG emissions associated with water supply were based on the estimated water usage by the proposed project (RBF 2005), the estimated electrical usage associated with supply, conveyance, treatment, and distribution of water (CEC 2006), and the same methodology as that for the project's electrical use. The business-as-usual scenario assumes that all of the project water would be provided as potable water from EMWD, while the proposed project would use reclaimed water from EMWD's San Jacinto wastewater treatment plant. *Tables 5.10-13 and*

[5] The GHG emission factor for Southern California Edison will be substantially lower in 2033 due to compliance with SB 107, SB 1368, and measures adopted under AB 32 to increase the renewable energy portfolio for utilities.

5.10-14 show the estimated GHG emissions associated with water provided to the project users under the business-as-usual and proposed project scenarios, respectively.

Similarly, wastewater treatment requires electricity and would generate its own GHG emissions. According to the *Local Governmental Operations Protocol* (CARB et al. 2008), CH_4 emissions are associated with unburned digester gas (which contains CH_4) and N_2O is associated with some types of wastewater treatment and discharged to aquatic environments. The electrical usage associated with wastewater treatment was estimated using the same references as those for water supply (RBF 2005 and CEC 2006). The population-based estimates from the *Local Governmental Operations Protocol* were used to estimate CH_4 and N_2O emissions from wastewater treatment processes.

Tables 5.10-13 and *5.10-14* show the estimated emissions of GHGs associated with water supply and wastewater treatment under the business-as-usual and proposed project scenarios, respectively. Additional details regarding these calculations are found in *Appendix I.*

Table 5.10-13 lists the operational emission sources of GHGs for the proposed project. The project is estimated to result in GHG emissions of approximately 49,650 metric tons CO_2E. While the proposed project would result in emissions of GHGs, no guidance exists to indicate what level of GHG emissions would be considered substantial enough to result in a significant adverse impact on global climate. However, it is generally the case that an individual project is of insufficient magnitude by itself to influence climate change or result in a substantial contribution to the global GHG inventory. Thus, GHG impacts are recognized as exclusively cumulative impacts; there are no non-cumulative GHG emission impacts from a climate change perspective (CAPCOA 2008). Accordingly, further discussion of the project's GHG emissions and their impact on global climate are addressed in *Section 6*.

Table 5.10-13
Estimated Business-As-Usual Operational Emissions of Greenhouse Gases

Source	Metric Tons CO_2E/Year	Percent of Total
Motor Vehicles	43,181	75.13
Area Sources		
Natural Gas Combustion	4,814	8.29
Hearth Combustion	19	0.03
Electrical Generation	4,694	8.17
Water Supply	4,340	7.55
Wastewater Treatment	429	0.75
Year 2033 Totals	**57,478**	**100.00%**

Table 5.10-14
Estimated Proposed Project Operational Emissions of Greenhouse Gases

Source	Metric Tons CO_2E/Year	Percent of Total
Motor Vehicles	36,488	73.49
Area Sources		
Natural Gas Combustion	4,814	9.70
Hearth Combustion	19	0.04
Electrical Generation	4,694	9.46
Water Supply	3,056	6.16
Recycled Water Supply	147	0.30
Wastewater Treatment	429	0.86
Year 2033 Totals	**49,648**	**100.00%**

Comparing the results in *Tables 5.10-3* and *5.10-14*, the proposed project would result in a GHG emission reduction of 7,830 metric tons CO_2E per year (14%) relative to the business-as-usual scenario. Implementation of the Specific Plan's Energy Efficiency Guidelines would provide additional benefits in terms of reduced natural gas and electrical usage and the associated GHG emissions. However, those emission reductions cannot be quantified because the Guidelines do not provide sufficient detail to compute the reduction in energy usage.

5.10.5 Mitigation Measures

Construction

5.10-a Consistent with SCAQMD Rule 403, it is required that fugitive dust generated by grading and construction activities be kept to a minimum with a goal of retaining dust on the site, by following the dust control measures listed below:

a) During clearing, grading, earth moving, excavation, or transportation of cut or fill materials, water trucks or sprinkler systems shall be used to prevent dust from leaving the site and to create a crust after each day's activities cease.

b) During construction, water truck or sprinkler systems shall be used to keep all areas of vehicle movement damp enough to prevent dust from leaving the site. At a minimum, this would include wetting down such areas later in the morning and after work is completed for the day and whenever winds exceed 15 miles per hour.

c) Soil stockpiled for more than two days shall be covered, kept moist, or treated with soil binders to prevent dust generation.

d) Reduce speeds on unpaved roads to less than 15 miles per hour.

e) Halt all grading and excavation operations when wind speeds exceed 25 miles per hour.

f) Dirt and debris spilled onto paved surfaces at the project site and on the adjacent roadways shall be swept, vacuumed, and/ or washed at the end of each workday.

g) Should minor import/export of soil materials be required, all trucks hauling dirt, sand, soil, or other loose material to and from the construction site shall be tarped and maintain a minimum two feet of freeboard.

h) At a minimum, at each vehicle egress from the project site to a paved public road, install a pad consisting of washed gravel (minimum-size: one inch) maintained in a clean condition to a depth of at least six inches and extending at least 30 feet wide and at least 50 feet long (or as otherwise directed by SCAQMD).

i) Review and comply with any additional requirements of SCAQMD Rule 403.

5.10-b The following shall be adhered to during project grading and construction to reduce VOC, NOx, and CO from construction equipment:

a) Heavy-duty diesel-powered construction equipment manufactured after 1996 (with federally mandated "clean" diesel engines) shall be utilized.

b) The engine size of construction equipment shall be the minimum size.

c) The number of construction equipment operating simultaneously shall be minimized through efficient management practices to ensure that the smallest number is operating at any on time.

d) Construction equipment shall be maintained in tune per the manufacturer's specifications.

e) Catalytic converters shall be installed on gasoline-powered equipment.

f) Diesel catalytic converters shall be installed.

g) Diesel powered equipment shall be utilized in lieu of electric equipment.

5.10-c The project developer shall use zero-Volatile Organic Compounds (VOC)-content architectural coatings during project construction/ application of paints and other architectural coatings to reduce ozone precursors. If zero-VOC paint cannot be utilized, developer shall avoid application of architectural coatings during the peak smog season: July, August, and September. Developer shall procure architectural coatings from a supplier in compliance with the requirements of SCAQMD's Rule 1113 (Architectural Coatings).

The following websites provide information/ lists of manufacturers related to zero-VOC content coatings:

http://www.aqmd.gov/prdas/brochures/paintguide.html

http://www.delta-institute.org/publications/paints.pdf

http://www.cleanaircounts.org/factsheets/FS%20PDF/Low%20VOC%20Paint.pdf

Operational

Substantial reductions in emissions from proposed land use-related sources would be difficult, as these sources would mainly be low-emitting, natural gas-fired units. Nonetheless, optimization of energy conservation techniques in proposed building design would minimize emissions resulting from lighting and space heating demands and help reduce the overall project significant impact of ROG and NO_x emissions. To help mitigate for operational impacts, the following shall occur.

5.10-d The applicant shall incorporate the following energy conservation measures into project building plans:

- Install low NO_x water heaters and space heaters
- Install heat transfer modules in furnaces
- Use light-colored, water-based paint and light-colored roofing materials to the satisfaction of the City.
- Install solar panels for water heating systems and other facilities and/or use water heaters that heat water only on demand.
- Use passive solar cooling/heating.
- Maximize the use of natural lighting.
- Install energy efficient appliances and lighting.
- Use landscaping to shade buildings and parking lots.

In addition to the above area source mitigations/required site design features, the following mitigation measures are required in order to minimize long-term vehicular impacts:

- Provide preferential parking spaces for employee carpools and vanpools in the commercial and business park land uses.
- Install covered bus stops to encourage use of mass transportation.
- Coordinate with the local transit agency to provide public transit to the project site.

- Develop, in coordination with the City of San Jacinto, public outreach programs to promote alternative methods of transportation.

5.10-e To mitigate the traffic conditions that could result in potential CO "hotspots", the project applicant shall participate in funding off-site traffic improvements which are needed to serve cumulative future traffic conditions through payment of appropriate traffic mitigation fees (Riverside County TUMF and City of San Jacinto DIF fees). TUMF provides a key funding source for General Plan improvements within the project area, including the required improvements related to the Ramona Expressway. (It should be noted that this mitigation measure also appears as Mitigation Measure 5.9-e.)

5.10.6 Residual Impacts/ Level of Significance after Mitigation

Implementation of the above mitigation measures would help reduce construction impacts; however, significant unmitigable impacts would remain. Operational impacts related to on-site and off-site odors and toxic air contaminants would remain or be mitigated to less-than-significant levels with mitigation. The combined contribution of the project's area source and vehicular emissions would remain significant and unmitigable despite identified mitigation measures.

5.11 NOISE

5.11.1 Introduction and Methodology

The following evaluation and discussion of potential noise impacts associated with the Villages of San Jacinto project implementation has been prepared as a complete technical noise study by Dudek.

This technical noise section evaluates noise effects of the project, including potential impacts from current and future ambient noise levels upon proposed land uses as well as noise generation potential from proposed land uses and activities within the Villages of San Jacinto Specific Plan area. Noise generation sources from future implementation of the Specific Plan include traffic, school-related playground and sports activity, and mechanical equipment and exterior activities from commercial uses.

Terminology Used to Describe Sound

Please refer to *Appendix J* for detailed definitions of technical terms used in the description and evaluation of noise. The following descriptions are provided for direct reference in reviewing the information in this section.

Sound is defined as any pressure variation detected by the human ear. The preferred unit for measuring sound is the decibel (dB). The dB expresses the logarithmic ratio of the amount of energy radiating from a source in the form of an acoustic wave. Zero dB corresponds approximately to the threshold of healthy human hearing, while 120 to 140 dB correspond to an average person's threshold of pain.

The human ear is not equally responsive to all frequencies of the audible sound spectrum. An electronic filter is normally used when taking noise measurements that de-emphasizes certain frequencies in a manner that mimics the human ear's response to sound; this method is referred to as A-weighting. Sound levels expressed under the A-weighted system are sometimes designated dB(A). All sound levels discussed in this report are A-weighted.

The equivalent continuous sound level (L_{eq}) is a single noise level that, if held constant during the specified time period, would represent the same total energy as a fluctuating noise. L_{eq} values are commonly expressed for periods of 1 hour, but longer or shorter time periods may be specified.

The noise descriptor Community Noise Equivalent Level (CNEL) is typically used when describing community noise. CNEL averages the varying sound levels occurring over a 24-hour period and gives a 10 dB penalty to noises occurring between the hours of 10:00 p.m. and

7:00 a.m. and a 5 dB penalty for noise between the hours of 7:00 p.m. to 10:00 p.m., to take into account noise sensitivity during nighttime and evening hours, respectively.

Noise Criteria

General Plan Noise Element Criteria:

The City of San Jacinto has an adopted Noise Element in the City's General Plan (City of San Jacinto 2006). The City's Noise Element identifies the limits for "normally acceptable" exterior ambient noise levels at residential land uses to be 65 dB CNEL. Also, the Noise Element stipulates that the interior noise level not exceed 45 dB CNEL within the habitable rooms of residences.

The Noise Element also identifies 65 dB CNEL and 45 dB CNEL as the maximum exterior and interior noise levels (respectively) for commercial land uses such as office, retail, reception, and restaurant. For parks and recreation facilities, the exterior limit is also proposed to be 65 dB CNEL, but the interior noise level is proposed to be 50 dB CNEL for this land use category.

Noise sources that are not directly related to transportation, such as construction, manufacturing or business operations; agricultural operations; and property maintenance activities should be controlled to minimize exposure to excessive noise levels and reduce the impacts of noise-producing land uses and activities on noise-sensitive land uses.

Municipal Code Noise Ordinance Criteria:

The City's noise ordinance (City of San Jacinto 2008) provides controls for excessive and annoying noise from stationary sources, such as air conditioning and refrigeration units, industrial development, and commercial activities. The ordinance also regulates construction activities within the City. Certain noise sources are prohibited, and the ordinance establishes an enforcement process.

Relative to construction noise, it is unlawful to create and emit noise from equipment operated during construction activities, whether on private property or within the public right of way between the hours of 7:00 p.m. of one day and 7:00 a.m. of the following day, and at any time on Sunday. Such equipment includes, but is not limited to, trucks, road graders, tractors, power saws, power drills, and generators.

5.11.2 Existing Conditions

Project Setting

The project site is generally located south of Ramona Expressway and adjacent to the west side of North Sanderson Avenue in the City of San Jacinto. The primary existing noise source at the site is vehicular traffic along North Sanderson Avenue. The current average daily traffic (ADT) volumes on North Sanderson Avenue are provided in *Table 5.11-1, Existing Average Daily Traffic Volumes near Villages of San Jacinto.*

Table 5.11-1
Existing Average Daily Traffic Volumes near Villages of San Jacinto

Location	Existing ADT

Sanderson Avenue (south of Ramona Boulevard)	12,800

SOURCE: Urban Crossroads 2009

Ambient Noise Monitoring

Since the primary existing noise source affecting the property is North Sanderson Avenue, an original noise measurement was conducted within the subject property boundaries and adjacent to Sanderson Avenue to determine the existing noise level associated with Sanderson Avenue, and for use in calibrating the noise model. The measurement was made using a calibrated Larson-Davis Laboratories Model 700 (S.N. 2132) integrating sound level meter equipped with a Type 2551 one-half-inch pre-polarized condenser microphone with pre-amplifier. When equipped with this microphone, the sound level meter meets the current American National Standards Institute standard for a Type 1 precision sound level meter. The sound level meter was positioned at a height of approximately 5 feet above the ground.

The original noise measurement location is depicted as Site 1 on *Figure 5.11-1, Noise Measurement Locations.* Site 1 is approximately 62 feet from the center line of Sanderson Avenue and is at approximately the same elevation as the roadway surface. The measured average noise level was 67 dB at Site 1. *Table 5.11-2, Measured Average Sound Level at Villages of San Jacinto Site,* shows the measured noise level and concurrent traffic volumes.

To more fully characterize existing noise conditions on the project site, a series of additional noise measurements were conducted. These supplemental noise measurement locations are depicted as Sites A to D on *Figure 5.11-1, Noise Measurement Locations.* The measured average noise levels at Sites A to D are illustrated in *Table 5.11-2, Measured Average Sound Level at Villages of San Jacinto Site.* Traffic counts were not conducted during the supplemental noise

measurements, because the locations were at distances beyond the area influenced by existing traffic noise sources.

Table 5.11-2
Measured Average Sound Level at Villages of San Jacinto Site

Site	Description	Date/Time	L_{eq} [1]	Cars	MT [2]	HT [3]
1	Approximately 62 feet to center line of Sanderson Avenue	11/01/2004 1:00 p.m. to 1:20 p.m.	67 dB	208	10	13
A	At property boundary for parcel to the northwest	7/8/2009 11:30 a.m. to 11:45 a.m.	39 dB	N.A.	N.A.	N.A.
B	At future Cawston Avenue alignment, just north of future De Anza Drive	7/8/2009 11:55 a.m. to 12:10 p.m.	41 dB	N.A.	N.A.	N.A.
C	Along Ramona Avenue, at northwest corner of property	7/8/2009 12:20 p.m. to 12:35 p.m.	40 dB	N.A.	N.A.	N.A.
D	Along future Bridge Street, at midpoint of southeast property line	7/8/2009 12:55 p.m. to 1:10 p.m.	42 dB	N.A.	N.A.	N.A.

NOTES: Temperature 70°, clear sky, 2 miles-per-hour northerly wind (November 1, 2004)
Temperature 88°, clear sky, 5 miles-per-hour southwest wind (July 8, 2009)

[3] Heavy trucks

Traffic Noise Modeling – Current Conditions

The existing CNEL along North Sanderson Avenue was determined based on the ambient noise measurement and using the current daily traffic volume for the road (with normalized medium and heavy truck percentages as provided by the County of Riverside) in the Federal Highway Administration's Highway Traffic Noise Prediction Model (FHWA 2004). For the current condition, the modeled CNEL at Site 1 is 72 dB (Dudek and Associates 2006). It should be noted that this noise level is in terms of the CNEL and not the L_{eq} as shown in *Table 5.11-2*.

The existing 65 dB CNEL contour from Sanderson Avenue within the Villages at San Jacinto project site is approximately 180 feet from the current center line of North Sanderson Avenue. The noise measurements conducted at interior portions of the site verify that most of the property is not directly affected by this traffic noise source, with average measured noise levels in the 39 – 42 dB range.

FIGURE 5.11-1

INTENTIONALLY LEFT BLANK

5.11.3 Significance Criteria

Based on the criteria identified in Appendix G of the CEQA Guidelines, the proposed project would have a significant impact on noise if it would result in:

1. The exposure of persons to or generation of noise levels in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies
2. The exposure of persons to or generation of excessive groundborne vibration or groundborne noise levels
3. A substantial permanent increase in ambient noise levels in the project vicinity above levels existing without the project.

A substantial temporary or periodic increase in ambient noise levels in the project vicinity above levels existing without the project.

5.11.4 Impacts

The project site would be exposed to existing and future traffic noise. Noise associated with the project would most likely result from project-generated traffic noise and noise from on-site commercial, school, and construction activities.

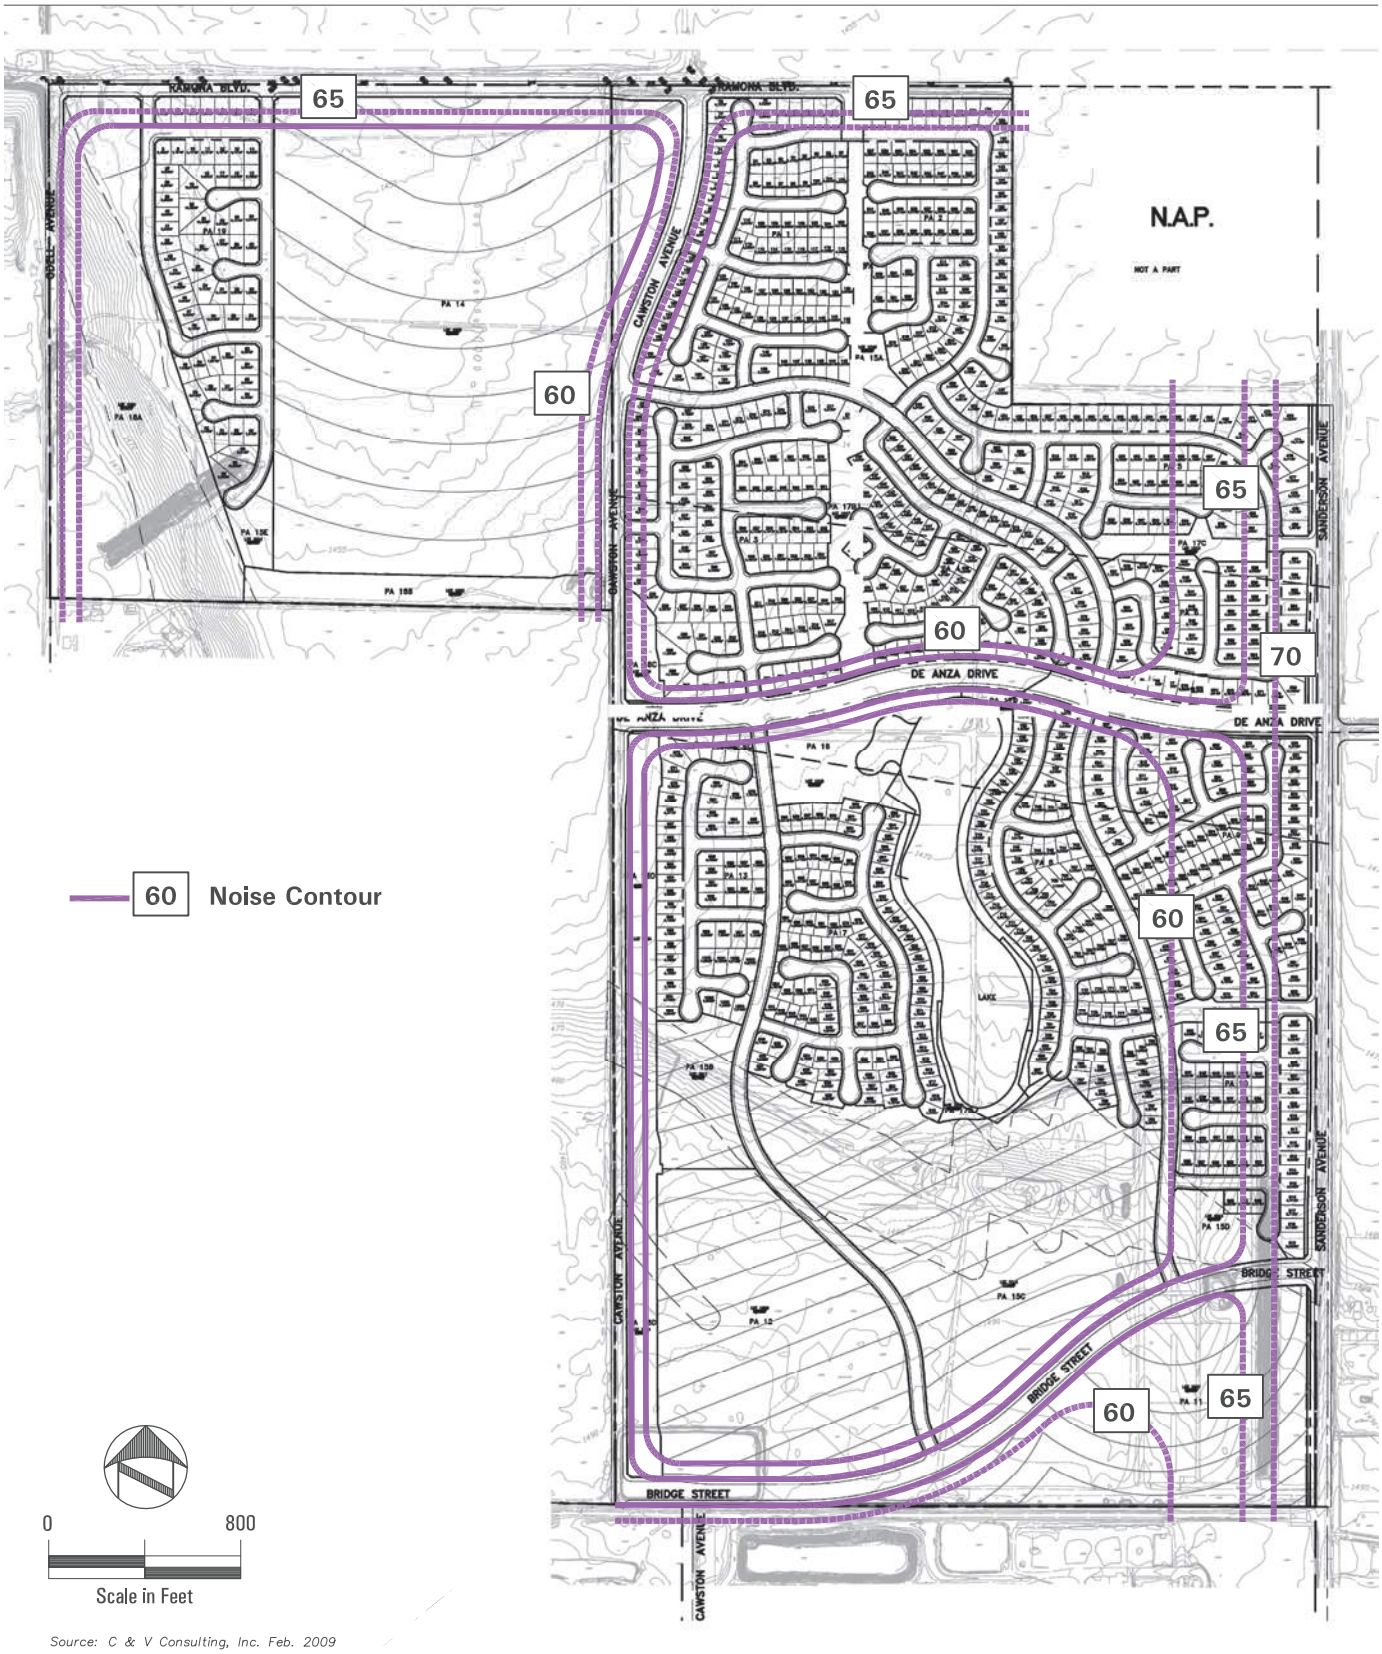
Would the project result in exposure of persons to or generation of noise levels in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies?

Traffic Noise Exposure

While only North Sanderson Avenue currently exists along the eastern boundary of the project site, the project site would eventually be served by three principal roadways oriented north/south and three principal roadways oriented east/west. The north/south roadways include Odell Avenue (western boundary), Cawston Avenue (central), and Sanderson Avenue (eastern boundary). The east/west roads include Ramona Boulevard South (northern boundary), De Anza Drive (central) and Bridge Street (southern boundary*). Figure 5.11-2, Noise Contours Associated with Future Roadways*, provides a graphical depiction of future roadway locations. These roadways are either on the boundary of the site or traverse the interior of the site and provide vehicular access from the site to the regional roadway network.

The public roadway system that abuts or traverses the site would carry project and regional traffic. To determine the future noise impact, City of San Jacinto General Plan build-out with project traffic volumes were used in the noise modeling (Urban Crossroads 2009). North Sanderson Avenue would have a future community build-out traffic volume ranging from 43,000

to 44,600 ADT adjacent to the project site. The other roadways would have future ADT volumes ranging up to 16,900 ADT along Ramona Boulevard; 6,800 ADT along Odell Avenue; 9,000 ADT along Cawston Avenue; 9,000 ADT along De Anza Drive and 7,000 ADT along Bridge Street. It should be noted that two new freeways, State Route 79 (SR 79) and Mid County Parkway (MCP) are currently in various planning stages. Detailed design drawings are not available for these two freeways. However, it is anticipated that the alignments of both freeways would be located at least 1,000 or more feet from the project site. As the area develops, there would be buildings and other structures that would most likely provide shielding between the freeways and the project site that would substantially attenuate the traffic noise. However, for the purposes of this study, it is conservatively assumed that the potential noise contribution from future SR 79 and MCP freeways would be 60 dB CNEL at the north and east boundaries of the project site.



Utilizing the planned roadway sections and identified future traffic volumes (from project development and full build-out of the General Plan), traffic noise along each of the project-related roadways was modeled. The results of the noise modeling for roadway traffic noise are presented in *Table 5.11-3, Modeled Future Sound Level along Project Roadways*.

Table 5.11-3
Modeled Future Sound Level along Project Roadways

Roadway	Distances from Center Line to CNEL Contours (feet)		
	70 db	65 db	60 db
Sanderson Avenue	220	350	650
Ramona Boulevard South	R/W [1]	110	170
Odell Avenue	R/W [1]	50	120
Cawston Avenue			
North of Bridge Street	R/W [1]	70	130
South of Bridge Street	R/W [1]	R/W [1]	90
De Anza Drive	R/W [1]	70	130
Bridge Street	R/W [1]	55	120

Villages of San Jacinto EIR

Noise Contours Associated with Future Roadways

FIGURE 5.11-2

INTENTIONALLY LEFT BLANK

Residential, commercial, school, and park land uses are proposed to be located immediately adjacent to the right-of-way for each of these roadway facilities with the exception of Odell Avenue. Therefore, with the exception of Odell Avenue, the potential exists for significant noise impacts to occur from exterior noise exposure above 65 dB CNEL for residential, commercial, school, and park uses located adjacent to the planned right-of-way for these roadway facilities. In order to reduce these potential impacts, mitigation is provided (see *Section 5.11.5, Mitigation Measures*, Mitigation Measures 5.11-a and 5.11-f).

Off-Site Noise Impacts Associated With Project Traffic

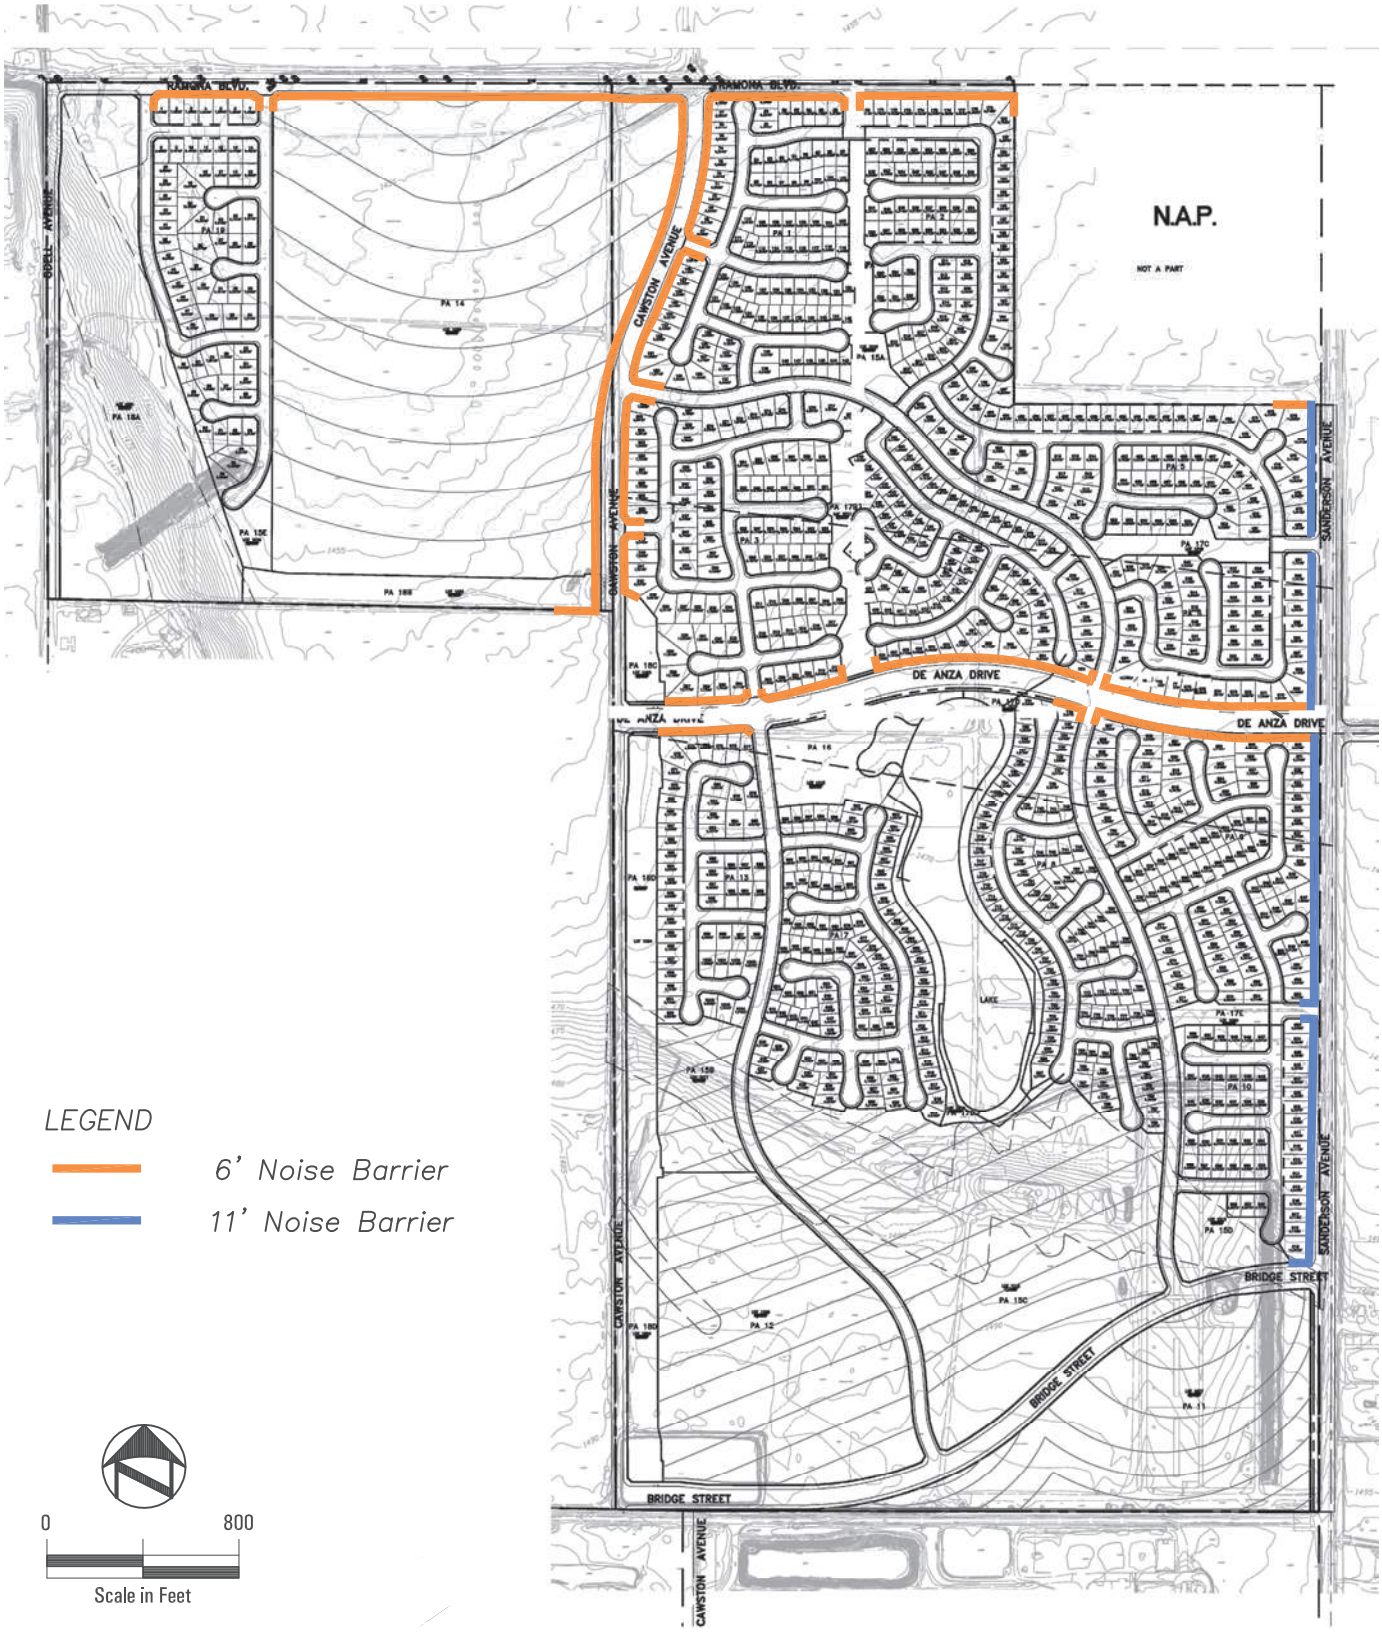
Traffic-related noise impacts, especially in the context of a Specific Plan analysis, must primarily evaluate the future noise environment resulting from long-range community build-out. This is performed by using the traffic volumes anticipated from General Plan build-out, as assessed by the assigned project transportation engineer. Future project traffic volumes within the development are largely derived from the project itself, and are addressed by noise barriers and other measures (see *Section 5.11.5, Mitigation Measures*, and *Figure 5.11-3, Noise Barrier Heights and Locations*). With distribution of project-generated trips onto the area roadway network off site, the noise attributable to project-contributed trips versus regional traffic becomes largely indistinguishable. An extensive level of cumulative development is anticipated to occur within the San Jacinto region. Sanderson Avenue is the primary off-site roadway that exists today and is that which will bear the majority of immediate project-related traffic. The noise level associated with the existing traffic volumes on Sanderson Avenue is compared against the noise levels resulting from existing-plus-project traffic (Phase I), and from traffic volumes for build-out of the General Plan (including the project volumes for Phases I–IV). The results are presented in *Table 5.11-, Project Contribution to Off-Site Traffic Noise (Off-Site Traffic Noise Level Increase).*

Table 5.11-4
Project Contribution to Off-Site Traffic Noise (Off-Site Traffic Noise Level Increase)

Street (Segment)	Existing ADT	Existing + Project (Year 2015) ADT	CNEL Increase[1] (dB)	Existing + General Plan Build-Out ADT	Existing + Project + General Plan Build-Out ADT	CNEL Increase[2] (dB)
Sanderson Avenue						
South of Ramona Blvd.	12,800	16,100	1	41,600	43,000	5
Cottonwood Ave. to future SR 79	13,700	15,900	1	53,200	61,600	7

[1] Existing vs. existing-plus-project noise increase
[2] Existing vs. General Plan build-out, including project

In the near term (year 2015), the project would increase the existing ambient noise level by 1 dB CNEL. This noise level increase is less than significant.



In the long term, the increase in traffic noise from the proposed project and cumulative developments (i.e., General Plan build-out) is calculated to range from 5 to 7 dB, which is a noticeable change in the noise environment. The noise increase associated with traffic from cumulative developments is therefore considered potentially significant. However, the project's contribution to cumulatively significant traffic noise impacts is less than significant (1 dB or less increase, which by itself is not a discernible increase). Consequently, mitigation is not required for the project's contribution to off-site noise impacts associated with General Plan build-out traffic volumes but is required for the cumulatively significant impact (see *Section 5.11.5, Mitigation Measures*, Mitigation Measure 5.11-a).

Noise Generation Associated with Commercial Land Uses

A retail commercial area and mixed-use area are proposed at the southern end of the subject property. The land uses at the commercial site could include neighborhood retail uses, such as a grocery store, drug store, cleaners, restaurants, fast food, and specialty stores. The mixed-use area could provide a broad range of land uses, including a library, police and fire facilities, dental and medical offices, real estate offices, banks, coffee shop, printers, and postal/shipping outlets. The commercial and mixed-use areas are generally buffered from on-site residential land uses by a park. The proposed commercial areas are located immediately adjacent to an existing off-site municipal wastewater treatment plant that would not be a noise-sensitive receptor. Residential land uses exist east of the proposed commercial area, across Sanderson Avenue; these residential land uses are currently protected by a sound-wall along Sanderson Avenue.

Sources of commercial and mixed-use noise typically include activities at loading/unloading docks and parking lots, heating/ventilation and air conditioning equipment (HVAC), maintenance activities, and additional truck traffic along adjacent roads.

Noise levels associated with the commercial and mixed-use activities would vary depending on the number of delivery trucks, loading dock areas, and customer traffic generated by the commercial site. Similarly, HVAC equipment noise would vary depending on the number and types of equipment selected. Typical roof-top HVAC packaged units generate noise levels of approximately 70 dB at 10 feet from the source. In order to avoid any potential impacts related to commercial use noise, mitigation is provided (see *Section 5.11.5, Mitigation Measures*, Mitigation Measure 5.11-b).

Villages of San Jacinto EIR

Noise Barrier Heights & Locations

FIGURE 5.11-3

INTENTIONALLY LEFT BLANK

School-Related Noise Concerns

A high school is designated as part of the proposed specific plan project. Schools are both noise-sensitive and noise generating. The high school would be located at the southwest corner of Ramona Boulevard and Cawston Avenue. The future exterior traffic noise at the high school site would exceed a CNEL of 65 dB as previously depicted in *Figure 5.11-2*. Traffic-related noise exposure levels within exterior use areas for the school (i.e., sports fields, athletic courts, etc.) could exceed acceptable noise standards, thereby resulting in potentially significant noise impacts. In order to avoid potentially significant noise impacts, mitigation is provided (see *Section 5.11.5, Mitigation Measures*, Mitigation Measures 5.11-c).

Future school buildings that are located in areas exposed to a noise level greater than 60 dB CNEL could exceed an interior noise level of 45 dB CNEL. In order to avoid these potentially significant impacts, mitigation is provided (see *Section 5.11.5, Mitigation Measures*, Mitigation Measure 5.11-c, 5.11-d and 5.11-e).

The proposed high school would be located adjacent to future residences along the west side of the site and also east of Cawston Avenue. Noise associated with schools generally consists of traffic noise and outdoor activities. Noise created by and emanating during the conduct of any authorized school activity upon school grounds is specifically excluded from the restrictions of the City's noise ordinance. However, some residents living adjacent to the high school may find the noise emanating from the school to be annoying. Therefore, a mitigation measure is provided to notify neighbors of the potential for this nuisance noise (see *Section 5.11.5, Mitigation Measures*, Mitigation Measure 5.11- d).

Short-Term Noise Impacts (Construction-Related Noise)

The applicant has indicated that build-out of the project would occur in four major phases, with construction beginning in 2011. Please refer to *Section 3.0, Project Description*, for a detailed discussion of the project phasing schedule and construction phasing exhibit. Because the development of the project would occur in distinct phases, portions of the development will be completed and occupied during the construction of subsequent project phases; the occupied project phases have the potential to be impacted by noise from ongoing construction activities.

Development activities for each phase of project construction would involve a four-step sequence: (1) demolition, (2) site preparation, (3) building construction, and (4) paving. Mass grading for the entire site would occur during Phase I. Specific project construction details and equipment fleet specifications are not available at this time; however, for the air quality analysis, a worst-case equipment fleet was derived. Please refer to *Table 5.11-3, Heavy Construction Equipment*, for an estimate of assumed heavy construction equipment requirements for project construction. The equipment information in *Table 5.11-3* is meant to represent a reasonable

worst-case estimate of construction equipment employment. As a summary, the derived equipment list for construction includes the following types of construction equipment:

- Tractor/Backhoe
- Bulldozer
- Loader
- Scraper
- Grader
- Off-Highway Water Truck
- Roller
- Crane
- Forklift
- Trencher
- Paving Equipment
- Paver
- Surfacing Equipment.

As demonstrated by the summary above, construction equipment anticipated for project development includes only standard equipment that would be employed for any routine construction project of this scale; construction equipment with substantially higher noise generation characteristics (such as pile drivers, rock drills, or blasting equipment) would not be needed for development of the proposed project. Based upon the standard construction equipment anticipated to be employed for project development, short-term noise associated with the grading and construction could result in maximum noise levels of up to approximately 90 dB measured 50 feet from the noise source (FTA 2006). Noise attenuation for a point source occurs over distance at a rate of approximately 6 dB every time the distance from the source is doubled. Therefore, at a distance of 900 feet from the source of the noise, noise attenuation would reduce typical construction-related maximum noise levels from 90 dB to 65 dB.

With respect to the proposed construction phasing schedule and the above discussion, constructed and occupied residences that are located within 900 feet of an area under construction could potentially experience nuisance noise (i.e., average noise levels above 65 dB).

The generation of noise from construction activities during sensitive time periods upon completed and occupied components of the project is considered a significant nuisance. As such, project-generated construction noise would pose a potentially significant effect on noise-sensitive

receptors if construction hour limitations are not imposed. However, with adherence to a restricted construction schedule dictating project-related site preparation and construction activities, consistent with the City's noise ordinance, significant construction-related noise impacts could be avoided. In order to avoid potentially significant construction-related noise impacts, mitigation is provided (see *Section 5.11.5, Mitigation Measures*, Mitigation Measure 5.11-f).

Would the project result in the exposure of persons to or generation of excessive groundborne vibration or groundborne noise levels?

Ground-borne vibration is typically attenuated over short distances. The heavier pieces of construction equipment that may be used at this site include a dozer, scraper, excavator and loaded materials trucks. These types of construction equipment would be located approximately 50 or more feet from the closest existing residences. Based on the anticipated construction equipment, the demolition of existing structures and excavation of the site could generate perceptible vibrations at some residences in the project vicinity. However, the vibration levels would be below levels that would significantly disturb the residences. Additionally, construction hours will be limited by the City's noise ordinance. Therefore, the potential vibration impacts to these residential structures are less than significant. Once construction is completed, the project would not generate groundborne vibration or groundborne noise levels.

Would the project result in substantial permanent increase in ambient noise levels in the project vicinity above levels existing without the project?

A permanent increase in ambient noise levels will occur in the project vicinity with implementation of the project due to added traffic volumes. However, as discussed above, the project's contribution to significant traffic noise impacts is less than significant (a 1 dB or less increase, which by itself is not a discernible increase).

5.11.5 Mitigation Measures

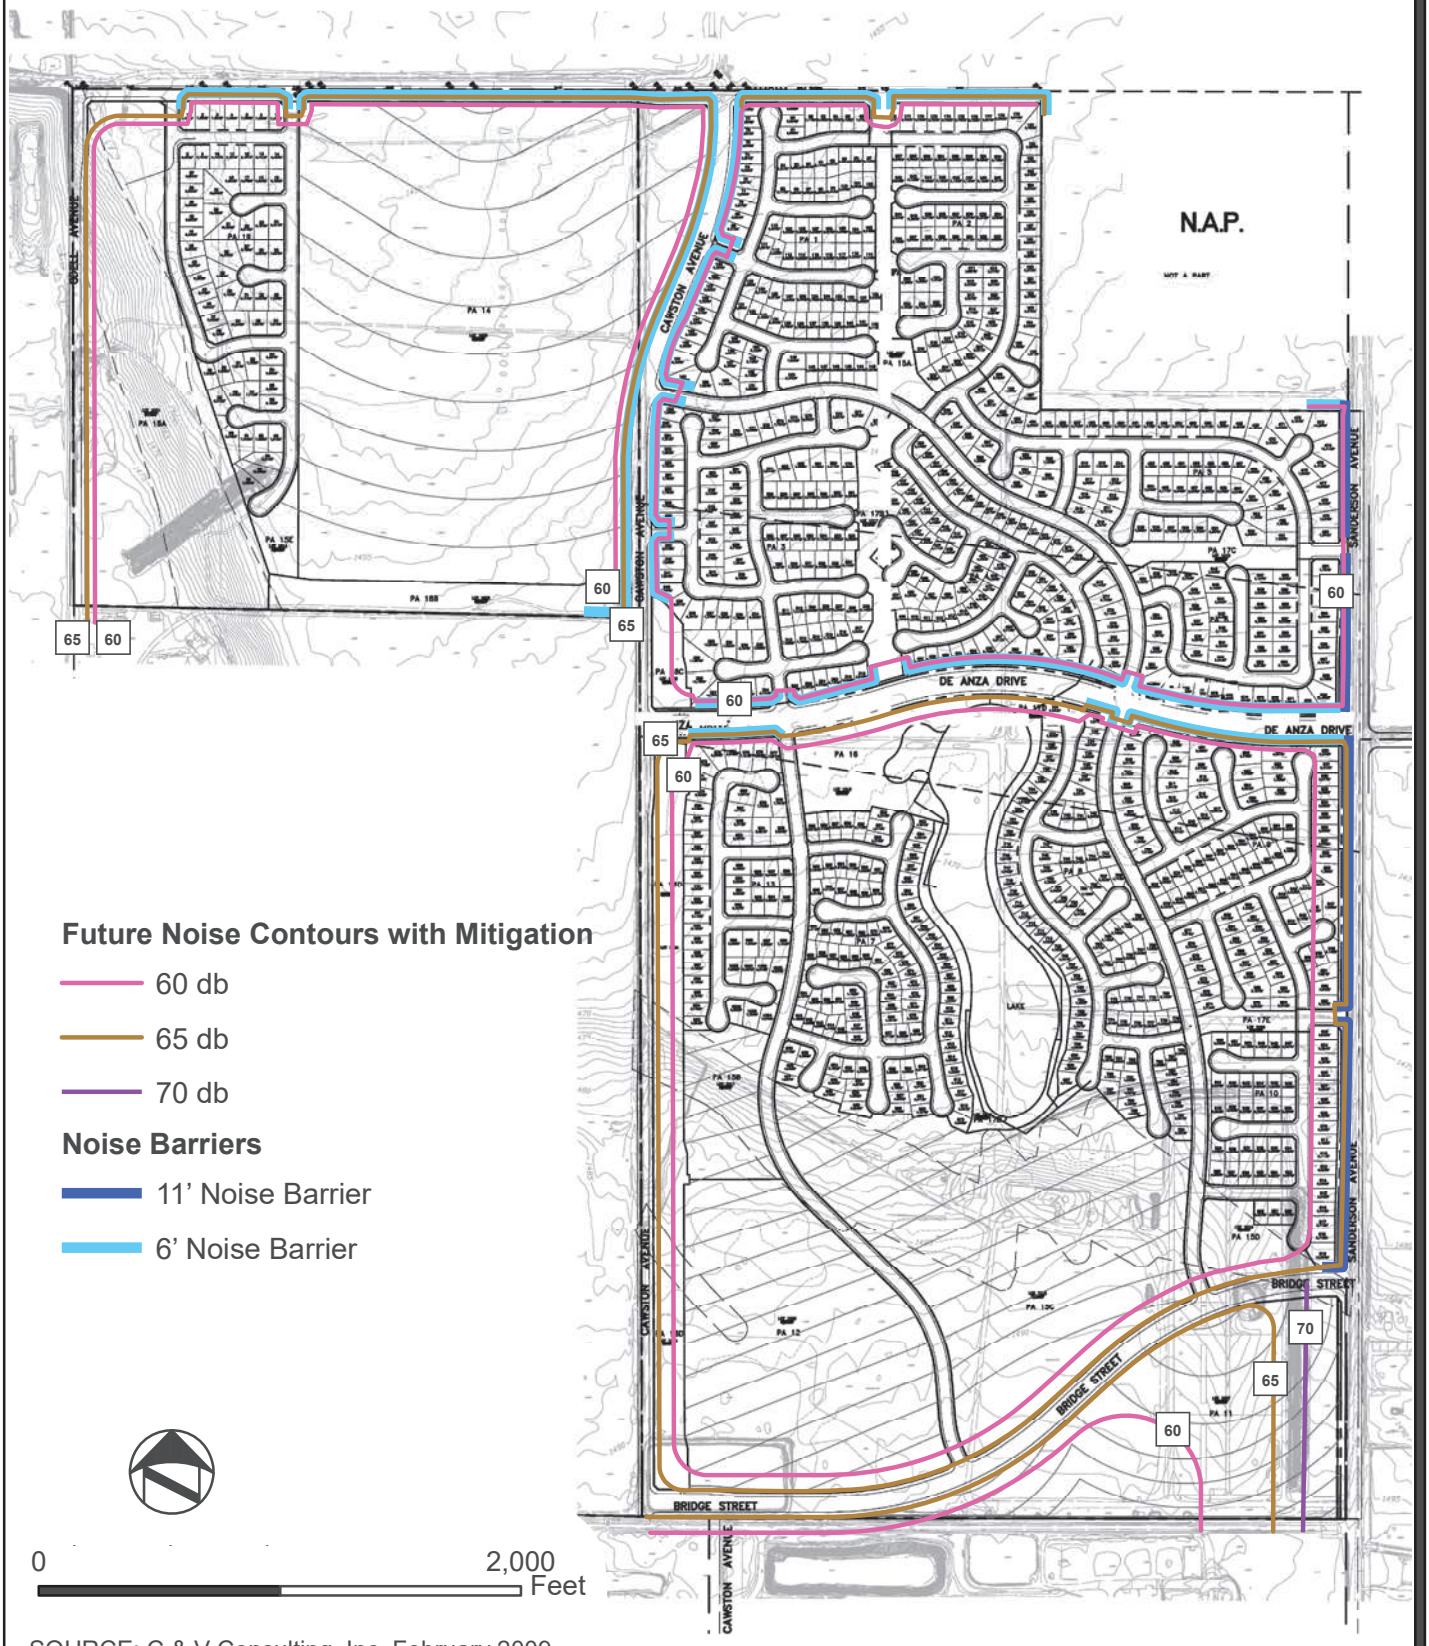
5.11-a Residential lots located adjacent to Sanderson Avenue shall include an 11-foot-high noise barrier; residential lots adjacent to Ramona Boulevard and Cawston Avenue (between Ramona Boulevard and De Anza Drive) shall require noise barriers a minimum of 6 feet in height. The project noise barriers must have a surface density of at least 4 pounds per square foot, and have no openings or cracks. The noise barriers may be constructed of acrylic glass, any masonry material, earthern berm, or a combination of these materials.

5.11-b Individual acoustical analyses shall be prepared as part of site plan/development plan review for future commercial development applications submitted to the City, to ensure noise levels would comply with the City's General Plan noise standards (maximum exterior noise levels of 65 dB CNEL; maximum interior noise levels of 45 dB CNEL) and not result in significant noise impacts at adjacent park land or residences. The

applicant for each commercial development proposal shall be required to commission or fund the required acoustical analysis. Although the future building-specific noise study will determine exact specifications, it is likely that interior noise mitigation would consist of sound-rated windows and mechanical ventilation systems for the commercial buildings. All required noise control measures identified in the acoustical analysis shall be made conditions of ultimate development approval to ensure that all measures are implemented to fully mitigate anticipated noise impacts.

5.11-c For the high school site, the specified noise barriers along Ramona Boulevard and Cawston Avenue shall be installed to protect exterior use areas of the site from traffic-related noise.

5.11-d A Notice-to-Property Owner shall be recorded on a separate buyer information sheet with the final map providing notice to potential future property owners in the vicinity of the school site (i.e., Planning Areas 1, 3, and 19) stating that they could be exposed to noise associated with outdoor activities at the high school. The disclosure will function to make potential buyers aware of the anticipated noise levels/impacts, such that particularly noise-sensitive individuals would have the opportunity to decide against purchase of a home which is subject to these periodic noise conditions.



5.11-e For residences proposed within the future 60 dB CNEL contour, an interior acoustical analysis shall be required prior to the issuance of building permits to ensure that the interior CNEL would not exceed 45 dB. Interior noise mitigation would most likely consist of sound-rated windows and mechanical ventilation systems for the homes. All required noise control measures identified in the acoustical analysis shall be made conditions of building permit issuance.

5.11-f Future project-related site preparation and construction activities shall be conducted in accordance with the City's noise ordinance. No construction shall occur Sundays or federal holidays (e.g., Thanksgiving, July 4th, Labor Day, etc.). Construction operation and equipment maintenance shall be limited to the hours of 7:00 a.m. to 7:00 p.m. Non-noise-generating construction activities, such as interior painting, are not subject to these restrictions.

5.11.6 Residual Impacts/Level of Significance after Mitigation

With implementation of the mitigation measures included in *Section 5.11.5* to ensure that adequate noise control elements are designed and implemented for the proposed development, potential noise impacts would be less than significant and residual impacts would not occur.

Figure 5.11-4 Noise Contours with Mitigation illustrates the residual noise levels under future traffic conditions, and with installation of prescribed noise walls.

5.12 PUBLIC SERVICES AND UTILITIES

5.12.1 Introduction and Methodology

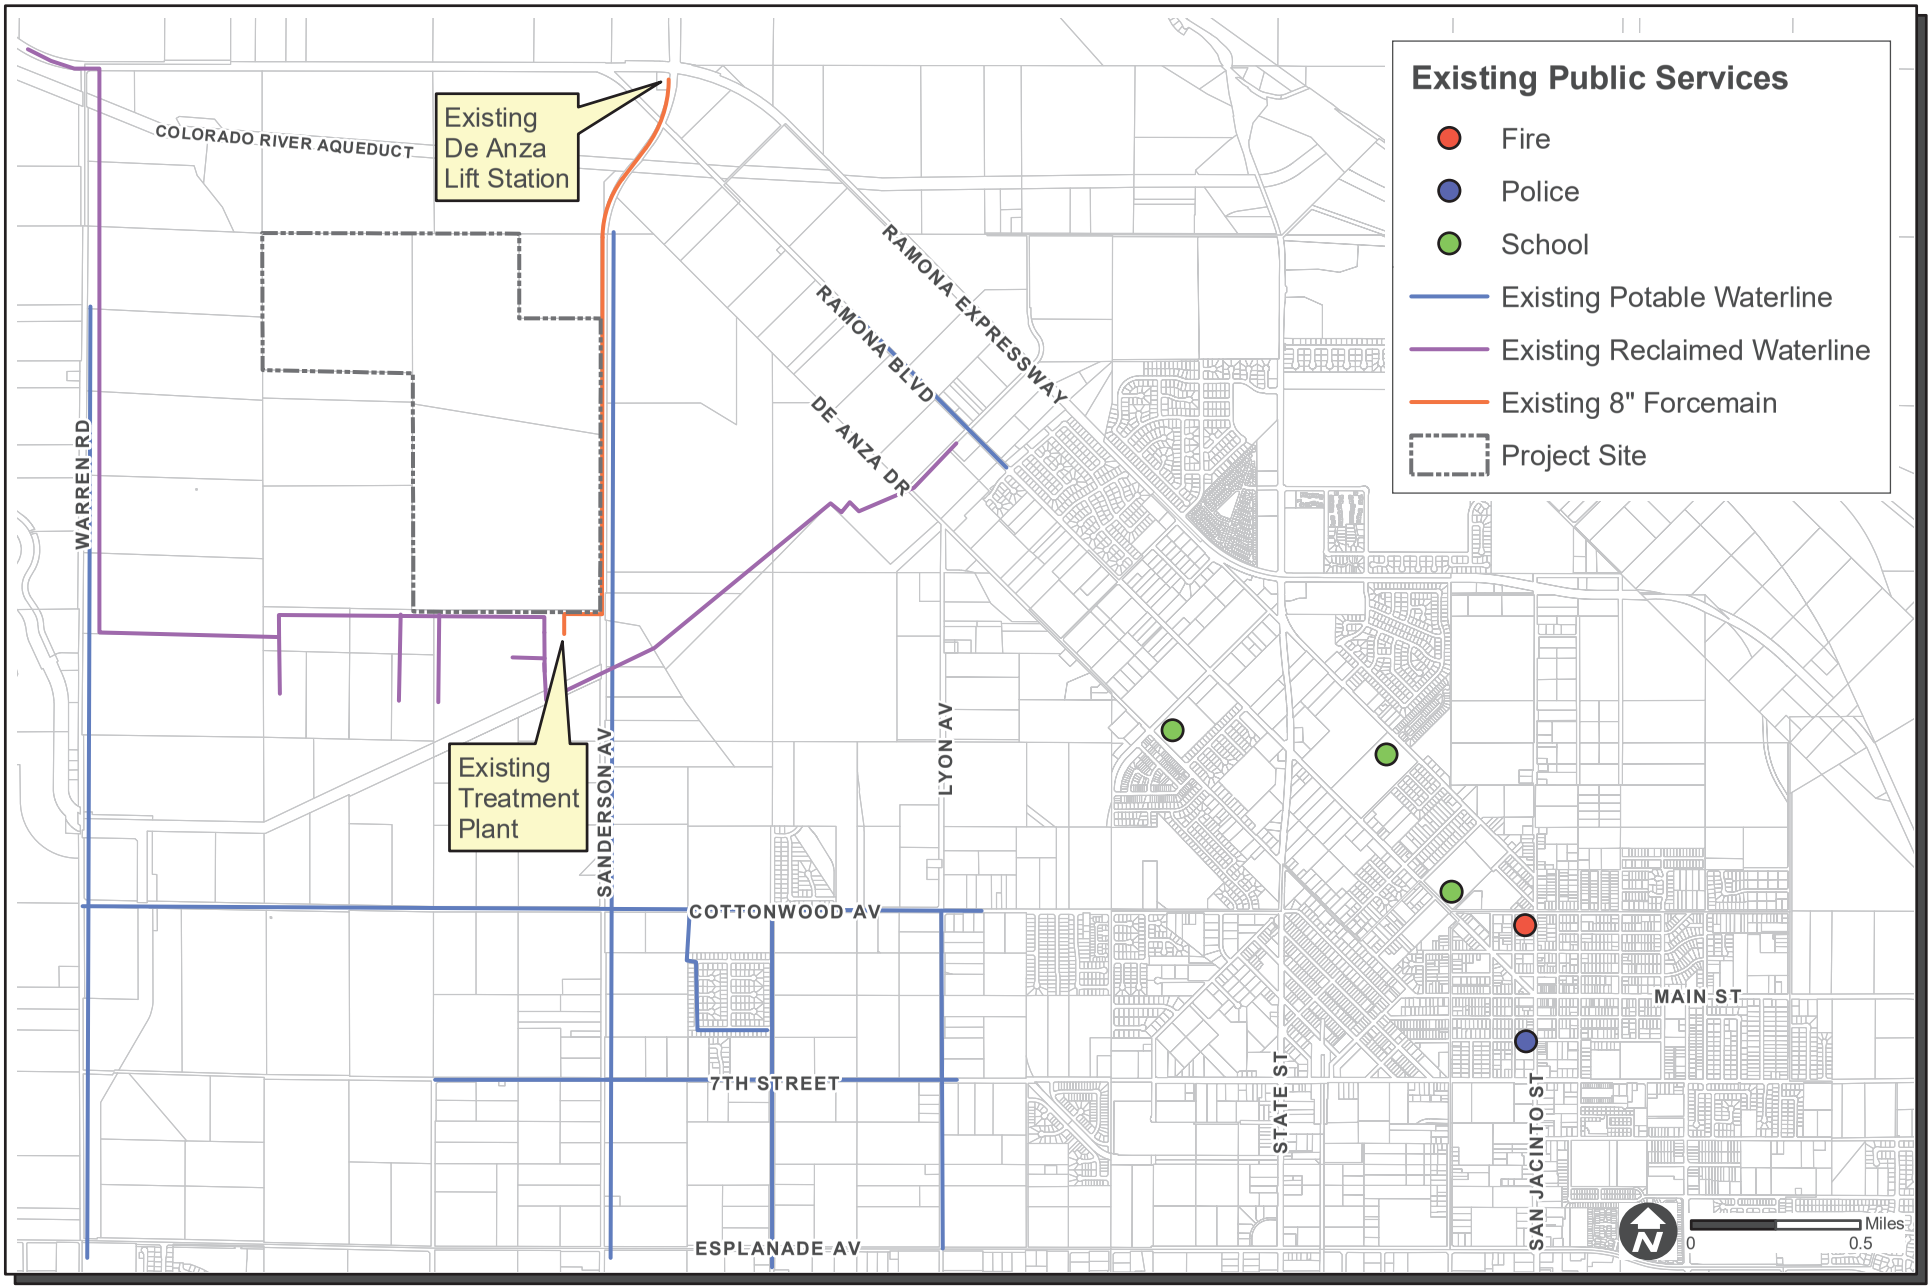
This section discusses public services and utilities necessary to serve the proposed Villages of San Jacinto and includes an analysis of potential project impacts to fire and police protection services, parks and recreation and, schools facilities; the availability of wastewater treatment facilities, stormwater drainage facilities, domestic water supply resources, and solid waste disposal and recycling.

Potential project impacts associated with increased demand on public services including fire, police, park and recreational facilities were evaluated per correspondence with City fire, police and regional park personnel and per the criteria identified in the City of San Jacinto Development Impact Fee Justification Study, prepared by David Taussig & Associates, Inc., approved by the City in October 2005. Impacts to school facilities associated from increased demand resulting from project development were analyzed pursuant to correspondence with school district personnel and utilizing the San Jacinto Unified School District Residential Development School Fee Justification Study and the Commercial/Industrial Development School Fee Justification Study prepared by David Taussig & Associates, Inc., February 13, 2004.

The availability of adequate domestic water supply and infrastructure necessary to serve the proposed Villages of San Jacinto area was determined by a Water Supply Assessment Report prepared by the Eastern Municipal Water District, December 15, 2004, and a letter dated May 11, 2009, confirming their previous conclusions. Both documents are included in *Appendix K*. In addition, the availability of water, wastewater and drainage facilities and related infrastructure required to serve the project were evaluated through a November 2005 Study prepared by RBF, the May 2006 Preliminary Drainage Study for TTM 34081 prepared by RBF, the August 2006 Phase 1, and 2 Drainage Study prepared by RBF, the December 12, 2006, Preliminary Drainage Analysis for Phases 1, 1A, 1B and 1C prepared by RBF and the February 23, 2009, *Preliminary Hydrology and Hydraulics Study for the Villages of San Jacinto* by JLC Engineering & Consulting Inc. (all included as *Appendix G*). Impacts associated with solid waste production and disposal and availability of recycling facilities were analyzed be means of evaluating the availability of sufficient landfill capacity to receive solid waste generated by the proposed development, including construction-generated wastes and projected, long-term residential and commercial-generated wastes, and the ability of the proposed development and City programs to meet State mandated recycling requirements.

Unlike other environmental impact sections in this EIR, this section is organized by category instead of a discussion of all existing conditions followed by significance criteria followed by impacts and finally a discussion of mitigation. *Section 5.12* is instead organized by topic. Each

topic includes a description of existing conditions, followed by significance criteria associated with the specific topic, impact assessment, mitigation measures and finally a discussion of the impact after mitigation. For example, Fire Protection – first a discussion of existing conditions is provided, then the relevant significance criteria related to fire protection, followed by an impact discussion on fire protection and finally a discussion of relevant mitigation measures. After a complete discussion of fire protection, police protection is provided and so on. It was determined that this method of analysis presentation would be easier to follow. Existing and Proposed Public Facilities and Service Systems are depicted on *Figures 5.12-1, Existing Public Services and Facilities, 5.12-2, Master Sewer Plan* and *5.12-3, Master Water Plan.*



5.12.2 Fire Protection

Existing Conditions

Fire protection services are provided throughout the City of San Jacinto under contract by the Riverside County Fire Department (RCOFD)/California Department of Forestry and Fire Protection (CAL Fire). The Departments provide services for fire suppression, emergency medical services, hazardous materials team response, fire prevention, public education, disaster preparedness and operations planning and staff training. The Riverside County Fire Department is staffed with 1,300 career employees (contracted from California Department of Fire), 300 Riverside County personnel, and 750 volunteer fire fighters, and currently serves approximately 1.6 million residents within an approximate area of 7,000 square miles. This service area consists of the unincorporated County areas, fourteen contract cities, one Community Service District, and one correctional corporation. The City of San Jacinto is served by Fire Station No. 25 located at 132 South San Jacinto Avenue, approximately 3 miles from the project area. Seven city firefighters (3 on duty each day) and approximately 5 volunteer personnel are assigned to Station No. 25 which maintains one city and one state fire engine. The City is also served by Station No. 78, located at 2450 West Cottonwood Avenue, approximately one mile south from the project site. This Station is currently staffed with 8 city firefighters and maintains one city fire engine for daily operations. (Personal Communication, Fire Captain Tim Chavez, June 25, 2009).

Significance Criteria

1. ***Would the project result in substantial adverse physical impacts associated with the provision of new or physically altered governmental facilities, need for new or physically altered governmental facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times or other performance objectives for fire protection?***

INTENTIONALLY LEFT BLANK

Impacts

The proposed Villages of San Jacinto is located within an existing fire protection service area. The City of San Jacinto Development Impact Fee Justification Study, states that City staff has determined existing public facilities to be sufficient to meet the current health, safety, and welfare needs of existing residents and employees (City of San Jacinto 2009). The development of the Villages of San Jacinto would result in an incremental increase in the local demand for fire services. Calls for emergency fire protection and emergency medical services generated from the new development are expected to be similar to that of other suburban residential and commercial areas within the City. Potential hazards and medical emergencies can be adequately addressed with the types of equipment typically found at City fire stations (e.g., response vehicles, EMT equipment) and the proposed project's internal circulation network would provide access to individual home sites and commercial areas from major roadways and would facilitate any necessary community evacuation plans.

The development of the Villages of San Jacinto would result in an incremental increase in demand for fire protection and emergency medical services and, when combined with the increased demand associated with other potential development projects within the project area, additional fire personnel, support staff, and related equipment and facilities would ultimately be required to effectively meet the demands of the proposed development and that of anticipated future development in the surrounding area.

Although the development of the proposed Villages of San Jacinto will not independently impact existing fire services, the City recognizes that new residential and non-residential development in the City within the next 15 years will generate additional residents and employees which will result in increased service calls and increased demand for fire protection personnel and facilities. The City of San Jacinto Development Impact Fee Justification Study identifies the City's determination that four new fire stations and one new fire training facility, and a number of additional service vehicles, will be needed to adequately service new development in the City within the next 15-year period. The Development Impact Fee Justification Study evaluates the need for new fire facilities as it relates to the level of service demanded by new development, which varies in proportion to the equivalent dwelling unit (EDU) generated by a specific land use. When evaluating the level of service demand for new fire protection facilities associated with new development, specific land uses (single family residential, retail commercial and non-retail commercial) are assigned an EDU factor that is derived from the number of persons per residential unit or the number of employees per commercial acreage.

The proposed development would result in a minor incremental increase in demand for fire protection services and, with consideration of future cumulative increases in demand for fire protection services associated with other development proposals and area-wide growth, could

potentially result in decreased levels of service within the project area and city-wide. The proposed project would, therefore, result in potentially significant cumulative impacts to fire protection services. However, feasible mitigation has been identified which would require the developer to pay appropriate development impact mitigation fees which would be used exclusively for future facility improvements as discussed above to ensure that the development contributes its fair share of the cost of the fire facilities and equipment determined to be necessary to adequately accommodate new development in the City. Development of the proposed school site into single-family homes, allowing for a maximum of 1,329 dwelling units would create the highest demand for fire protection services. Implementation of *Mitigation Measure 5.12-a* would ensure that the appropriate mitigation fees are contributed by the development to aid in acquiring the additional resources needed to reduce potential cumulative impacts to fire services to less than significant levels. Therefore, cumulative impacts associated with fire protection services are potentially significant. In order to avoid potential impacts, mitigation is provided (see *Section 5.12.5, Mitigation Measures, Mitigation Measure 5.12-a*).

Mitigation Measures

5.12-a The Developer shall be required to pay the Development Impact Mitigation Fees, as determined to be necessary by the development agreement, City Community Development Department and Public Works Department to offset impacts on City fire services. The current fee amount is outlined in *Table 5.12-1, Fire Facilities Fee Derivation Summary*.

Table 5.12-1
Fire Facilities Fee Derivation Summary*

Land Use	Residents/ Employees per Unit/Acre	EDUs per Unit/Acre	Number of Proposed EDUs/Acres	Development Impact Fee per Unit/Acre	Total Facility Impact Fee
Single Family	3.05	1.00	1,329**	$212	$281,748
Retail Commercial	15.03	4.93	22.7	$1,042	$23,653
Non-Retail Commercial	12.70	4.16	26.3	$880	$23,144
				Total	**$328,545**

* Fees are based on those established by the City at the time this RDEIR No. 2 was prepared. Fees may be adjusted in the future as building permits are requested for each specific phase.
** Assumes worse-case scenario that the proposed school site will be developed into single-family homes

Residual Impacts/Level of Significance after Mitigation

The proposed Villages of San Jacinto Specific Plan includes development standards that would apply to all future build-out of the planning area which specifically includes development elements and/or policies and measures to ensure that adequate public facilities and services such

as fire protection are provided in conjunction with build-out of the development. With implementation of the additional mitigation measure above, impacts to fire protection services/facilities would be less than significant.

5.12.3 Police Protection

Existing Conditions

The San Jacinto Police department, located approximately three miles from the project area at 160 West Sixth Street, provides police protection in the City of San Jacinto. As of May 2009, police services are provided throughout the City of San Jacinto under contract by the Riverside County Sheriff's Department. The police department employs a total of 48 staff employees, consisting of 39 sworn personnel (including the police chief, captains, detectives, juvenile officer, and training support supervisor) and 9 non-sworn personnel (community service officers, dispatch supervisor, dispatchers, communications specialist); and maintains 22 marked patrol units, 8 unmarked units and 3 volunteer automobiles. The Department operates in 3 shifts per day, consisting of 3 deputies and 1 sergeant. Emergency call response times for priority 1 calls in the City of San Jacinto average just over four minutes, which is considered slightly below the average and acceptable response times defined by the County Sheriff's Department for other contract City and County police departments. (Personal Communication, Sergeant Brian Tonseth, June 26, 2009).

Significance Criteria

2. ***Would the project result in substantial adverse physical impacts associated with the provision of new or physically altered governmental facilities, need for new or physically altered governmental facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times or other performance objectives for police protection?***

Impacts

The proposed project would result in a maximum of 1,329 residential dwelling units, assuming that the proposed high school would be developed with single-family homes. The development of the school site into single-family homes would create the greatest impact to police protection services and, therefore, that scenario is analyzed. In addition, the proposed project would include public parks and other passive recreational facilities, 22.7 acres of general commercial development, and 26.3 acres of mixed-use development. The proposed Villages of San Jacinto is serviced by the City of San Jacinto Police Department which currently maintains acceptable levels of emergency call response times as defined by the County Sheriff's Department for other contract City and County police departments. The development of the Specific Plan area would

result in an incremental increase in the local demand for police services. Police personnel have indicated that the project area is located in a relatively rural area of limited development where few calls are currently received and attended; therefore, project development will likely result in an increase in the Department's average response time when attending calls from the proposed development (Tonseth, personal communication, June 26, 2009).

The development of the Villages of San Jacinto would result in an incremental increase in demand on police services and, when combined with the demand associated with anticipated population growth and other potential development projects within the project area, additional police personnel, support staff, and related equipment and facilities would be required to effectively meet the demands of the proposed development as well as anticipated future development in the surrounding area. However, the increased demand that would occur with development of the Villages of San Jacinto would be a small portion of the anticipated area-wide increased demand associated with overall population growth and other development projects within the project area. Therefore, increased demand for police protection services resulting from development of the Villages of San Jacinto would be minor and incremental in nature and is not expected to substantially diminish existing service levels of police response or necessitate the construction of any new police facilities (or the expansion of any existing police facilities) that could entail changes in the physical environment. Therefore, impacts to police services would be less than significant.

Although the development of the proposed Villages of San Jacinto would not independently impact existing police services, the City recognizes that new residential and non-residential development in the City of San Jacinto within the next 15-years would generate additional residents and employees, which would result in increased service calls and increased demand for police protection personnel and facilities. The City of San Jacinto Draft Development Impact Fee Justification Study identifies the City's determination that one new police facility and a number of additional service vehicles would be needed to adequately service new development in the City within the next 15-year period. The Draft Development Impact Fee Justification Study evaluates the need for new police facilities as it relates to the level of service demanded by new development, which varies in proportion to the equivalent dwelling unit (EDU) generated by a specific land use. When evaluating the level of service demand for new police protection facilities associated with new development, land uses are assigned an EDU factor that is derived from the number of calls for police services generated for specific land uses (single family residential, multiple family residential, retail commercial, and non-retail commercial).

The proposed development would result in a minor incremental increase in demand for police services and, with consideration of future cumulative increases in demand for police services associated with other development proposals and area-wide growth, could potentially result in decreased levels of service within the project area and city-wide. The proposed project would,

therefore, contribute to potentially significant cumulative impacts to police services. However, feasible mitigation has been identified which would require the developer to pay appropriate development impact mitigation fees which would be used exclusively for the future facility improvements as discussed above to ensure that the development contributes its fair share of the cost of the police facilities and equipment determined to be necessary to adequately accommodate new development in the City. Therefore, cumulative impacts associated with police services are potentially significant. In order to reduce potential impacts, mitigation is provided (see *Section 5.12.5, Mitigation Measures, Mitigation Measure 5.12-b*).

Mitigation Measures

5.12-b The Developer shall be required to pay the Development Impact Mitigation Fees, as determined to be necessary by the development agreement, City Community Development Department and Public Works Department to offset impacts on police services. Current fee amounts are summarized in *Table 5.12-2, Police Facilities Fee Derivation Summary*.

Table 5.12-2
Police Facilities Fee Derivation Summary*

Land Use	Call Generation Rate	EDUs per Unit/Acre	Number of Proposed EDUs	Development Impact Fee per Unit/Acre	Total Facility Impact Fee
Single Family	3.05	1.00	1,329**	$198	$263,142
Retail Commercial	15.03	4.93	22.7	$2,012	$45,672
Non-Retail Commercial	12.70	4.16	26.3	$2,012	$52,916
				Total	**$361,730**

* Fees are based on those established by the City at the time this RDEIR No. 2 was prepared. Fees may be adjusted in the future as building permits are requested for each specific phase.
** Assumes worse-case scenario that school site will be developed into single-family homes

Residual Impacts/Level of Significance after Mitigation

The proposed Villages of San Jacinto Specific Plan includes development standards that would apply to all future build-out of the planning area which specifically includes development elements and/or policies and measures to ensure that adequate public facilities and services such as police protection are provided in conjunction with build-out of the development. With implementation of the additional mitigation measure above, impacts to police protection services/facilities would be less than significant.

5.12.4 Parks and Recreation

Existing Conditions

The City of San Jacinto owns and maintains three parks throughout the City including Salle Park (3.5 to 4 acres) located near Monte Vista School, Mistletoe Park (5 acres) located on Main Street, and Rancho San Jacinto Park (7 acres). In addition, a 36-acre regional park, owned and operated by the Valley Wide Park and Recreation District, is located at 901 W. Esplanade in San Jacinto and includes a 22,000-square-foot sports center, six lighted tennis courts, seven baseball/softball diamonds, six soccer fields, picnic areas with barbecues and play equipment, batting cages, administration offices, outside basketball and volleyball courts, and six horseshoe pits. None of these park facilities are located in the vicinity of the proposed Villages of San Jacinto project site.

The City's General Plan Land Use Map indicates that a total of approximately 44.7 acres of land area on the project site is currently designated for Open Space- Recreation (OS-R) land use. The General Plan indicates that the OS-R category allows for preservation of open space as well as outdoor recreational facilities.

Significance Criteria

3. ***Would the project result in substantial adverse physical impacts associated with the provision of new or physically altered governmental facilities, need for new or physically altered governmental facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times or other performance objectives for parks?***

Impacts

As seen in *Table 5.12-3, Proposed Open Space Designation,* the proposed Villages of San Jacinto project includes a total of 105.4 acres of open space/recreation uses. There will be a total of 43 acres of parks provided on site, including three public parks (40.8 acres) and two private neighborhood parks (2.2 acres). The largest of these parks is the 33.4-acre public Community Park north of Bridge Street in the southern portion of the proposed development. Other recreational amenities include a 5.1-acre Lake House Beach Club and Swim Lagoon. The 11-acre private lake will be located adjacent to the Swim Lagoon. It will feature a concrete trail surrounding lake and connecting to the community park. A total of 9.6 acres of landscaped walkways or "paseos" will serve as pedestrian linkages between land uses and will create landscaped buffer areas between Planning Areas. These paseos will be a minimum of 50 feet wide and have 10-foot-wide concrete trails. The proposed Villages of San Jacinto would result in

an increase in the 44.7 acres of land area within the project area presently designated for open space to a total of 105.4 acres.

Table 5.12-3
Proposed Open Space Designation

Land Use Type	Acres
Public Neighborhood and Community Parks	40.8
Private Neighborhood Parks	2.2
Paseos	9.6
Drainage/Basins	15.2
Lake Surfaces	11.0
Landscape Easements	2.4
Water Quality Detention Basin	24.2
Total	**105.4**

The City's General Plan requires that developers of residential projects provide adequate parkland equal to 5 acres per 1,000 residents and non-residential development provide parkland equal to 2.5 acres per employee. Based on factors in the Development Fee Justification Study (*Table 5.12-1*), the project would result in up to 4,054 residents (1,329 units × 3.05 residents per dwelling unit) creating the need for 20 acres of parkland. Employees associated with the project would create the need for approximately 2 acres of parkland for a total of 22 acres. Since the project provides 41 acres of public parkland, it would exceed the General Plan requirement and no mitigation is required. It should be noted that, in the previous recirculated DEIR (January 2007), a park mitigation fee was required due to the private nature of proposed parks. Because the project provides adequate public parkland, this is no longer the case and the fee is not required. Therefore, development of the Villages of San Jacinto would have an overall beneficial impact to the supply of park land and recreational opportunities to new residents of this community and the public.

Mitigation Measures

None.

Residual Impacts/Level of Significance after Mitigation

The proposed Villages of San Jacinto Specific Plan includes development standards that would apply to all future build-out of the planning areas. These standards specifically include development elements and/or policies and measures to ensure that adequate public facilities and services, such as parks and recreational facilities, are provided in conjunction with build-out of the development. Therefore, impacts to parks and recreational facilities would be less than significant.

5.12.5 Schools

Existing Conditions

The project site is located in the San Jacinto Unified School District (SJUSD) which serves approximately 7,000 students in eight primary K-5 schools, two middle 6–8 schools and two 9–12 high schools (website accessed May 5, 2009, http://www.sanjacinto.k12.ca.us/). The City's Land Use Map indicates that two future school sites are planned at the project site.

The closest existing elementary school site to the project area is De Anza Elementary located at 1089 De Anza Drive. The proposed project includes a potential new high school facility which would serve students of the proposed development. Should the proposed high school site not be included in the final build-out of the development, San Jacinto High School, located at 500 Idyllwild Drive, would accommodate high schools students from the project area. Monte Vista Middle School, located at 181 North Ramona Boulevard, would accommodate middle school students from the project area.

According to the San Jacinto Unified School District Residential Development School Fee Justification Study, prepared by David Taussig & Associates, Inc., February 13, 2004, the overall capacity of the District facilities was 7,456 students (including the addition of 7 portables at the elementary level), determined per Section 17071.10 of the California Education Code. The Study determined that of the 7,456 seats, 4,065 were at the elementary level, 1,418 were at the middle-school level, and 1,973 were at the high school level. The study determined that student enrollment in the 2003–2004 school year exceeded the District's facilities at the elementary level, but fell 354 and 158 seats short of the District's middle and high school capacity levels, respectively.

District personnel have indicated that facilities of the San Jacinto Unified School District currently exceed design capacity and the District has been adding additional portable classrooms to accommodate enrollment levels. Of the thirty portable classrooms currently planned to be installed, twenty will be used for elementary students and ten will be used for middle school students. In addition, the District is currently pursuing two new elementary school sites; however, these planned school sites are incorporated into other development proposals and would not accommodate new students generated by the proposed development (Arthur 2004).

Significance Criteria

4. ***Would the project result in substantial adverse physical impacts associated with the provision of new or physically altered governmental facilities, need for new or physically altered governmental facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios,***

response times or other performance objectives for fire other public facilities such as schools?

Impacts

The proposed project would result in development of a maximum 1,329 dwelling units, assuming worse case that the proposed school site is developed into single-family homes. The proposed project would also include 22.7 acres of general commercial development, a 26.3-acre mixed-use development, and would also potentially include a 69.1 acre site for a new high school that would accommodate up to 2,000 students. However, as discussed above, existing school facilities in the City are currently at capacity or exceeding capacity at all education levels and the development of future residences on the property would produce new demand for school resources. As such, new development in the City of San Jacinto would result in an increase in residents and employees within the City and would thereby increase demand on school facilities potentially resulting in a significant impact to schools which are already at or approaching maximum enrollment capacity levels.

The San Jacinto Unified School District utilizes student generation rates as published in the District's Residential Development School Fee Justification Study and the Commercial/ Industrial Development School Fee Justification Study to determine the projected number of students that would be generated for a new development proposal. *Table 5.12-4, Residential Project Student Generation,* contains the anticipated student generation that would result from the proposed residential development and *Table 5.12-5, Commercial Project Student Generation,* contains the anticipated student generation that would result from the proposed commercial development. The total projected student generation is based on student generation factors contained in the Residential Development School Fee Justification Study and the Commercial/Industrial Development School Fee Justification Study as provided by the School District.

Table 5.12-4
Residential Project Student Generation

School District/ Grade Level	Residential Unit Type	# of Units	Generation Factor (Students/Unit)	Total Students
Proposed Project				
Elementary				
K–6	Single-Family	1,329[1]	0.4832	642
Middle School				
7–8	Single-Family	1,329[1]	0.1320	175
High School				
9–12	Single-Family	1,329[1]	0.2302	306
			Total Student Generation	**1,123**

[1] Assumes worse-case scenario that proposed school site will be developed into single-family homes

Based on the proposed number and type of residential units and student generation rates as presented in *Table 5.12-3, Residential Project Student Generation*, the proposed project would generate 642 elementary school students, 175 middle school students and 306 high school students. A total of 1,123 students would be generated by the proposed residential development. In addition, based on the proposed land use type and the amount of new commercial square footage, and student generation rates as presented in *Table 5.12-5, Commercial Project Student Generation*, the proposed project would generate 93 elementary school students, 25 middle school students and 45 high school students for a total of 163 new students and a combined total of 1,286 students.

Table 5.12-5
Commercial Project Student Generation

School District/ Grade Level	Proposed Land Use	Square Footage	Student Generation/ 1,000 Square Feet	Total Students
Elementary				
K–6	Retail	247,000	0.1188	29
	Mixed-Use	343,400	0.1856	64
			Subtotal K–6	*93*
Middle School				
7-8	Retail	247,000	0.0322	8
	Mixed-Use	343,400	0.0503	17
			Subtotal 7–8	*25*
High School				
9-12	Retail	247,000	0.0572	14
	Mixed-Use	343,400	0.0895	31
			Subtotal 9–12	*45*
			Total Student Generation	**163**

The proposed project would be required to pay state-mandated school facilities fees (per Government Code Section 65996) at a maximum of $4.46 per residential square foot and $0.47 per square foot of new commercial development per current requirements. These fees may be adjusted by the state in the future as building permits for each phase are requested. Payment of such fees represents full mitigation for impacts to schools (see *Section 5.12.5, Mitigation Measures, Mitigation Measure 5.12-c*). Additionally, the proposed project would potentially include the designation of a new 69.1-acre high school site, to be located in the northwest portion (PA 14) of the site, which would accommodate the additional high school students that would be generated by the proposed development.

As discussed above, it is anticipated that the proposed high school site would accommodate 2,000 students. Provision of this school facility in the Villages of San Jacinto Specific Plan would serve new students generated by the proposed development as well as students from adjacent neighborhoods. Payment of state mandated fees will help to offset the cost of this facility.

Mitigation Measures

5.12-c The Developer shall be required to pay the Development Impact Mitigation Fees, as determined to be necessary by the development agreement, City Community Development Department, Public Works Department and San Jacinto School District, to offset impacts on school facilities.

Requiring payment of the school facility mitigation fees would aid in acquiring the additional resources to provide adequate school facilities necessary to accommodate existing and future residents. Therefore, contribution of the mitigation fees by the developer would ensure that adequate mitigation is provided to reduce potential direct and cumulative school impacts to less than significant levels. Should the developer assist the City in facilitating the construction of the school site identified in the Specific Plan, the City may decide to waive or reduce some portion of the school mitigation fees typically required to an appropriate lesser amount in consideration of the partial mitigation provided by developer-assisted, on-site school facility construction.

Residual Impact/Level of Significance after Mitigation

The proposed Villages of San Jacinto Specific Plan includes development standards that would apply to all future build-out of the planning area which specifically includes development elements and/or policies and measures to ensure that adequate public facilities and services such as schools are provided in conjunction with build-out of the development. With implementation of the additional mitigation measure above, impacts to schools would be less than significant.

5.12.6 Wastewater Treatment

Existing Conditions

Wastewater treatment for the City of San Jacinto is provided by the Eastern Municipal Water District (EMWD) Hemet/San Jacinto Regional Water Reclamation Facility. The facility collects and treats municipal sewage and produces recycled water for reuse. According to the Eastern Municipal Water District's wastewater treatment website page for the Hemet/San Jacinto Regional Water Reclamation Facility the facility currently maintains a typical daily treatment flow of 7.8 million gallons a day (MGD) and a maximum raw sewage treatment capacity of 11

MGD. The facility is slated for an expansion to provide a maximum of 27 MGD treatment capacity to accommodate projected future sewage production from growth in the facility's service area (EMWD, http://www.emwd.org/news/Insights/insights_hemet-san_jacinto.pdf accessed May 5, 2009). All EMWD facilities are currently determined to be in compliance with Regional Water Quality Control Board wastewater treatment requirements. Currently, there is an existing force main located within the Sanderson Avenue right-of-way along the east property boundary. The existing De Anza lift station located at the northeast corner of the project area conveys flows through the sewer main to the Hemet/San Jacinto Regional Water Reclamation Facility located directly south of the project site.

Significance Criteria

5. ***Would the project exceed wastewater treatment requirements of the applicable Regional Water Quality Control Board?***

6. ***Would the project require or result in the construction of new water or wastewater treatment facilities or expansion of existing facilities, the construction of which would cause significant environmental effects?***

7. ***Would the project result in determination by the wastewater treatment provider which serves or may serve the project that it has adequate capacity to serve the project's projected demand in addition to the provider's existing commitments?***

Impacts

Wastewater treatment for the City of San Jacinto is provided by the EMWD Hemet/San Jacinto Regional Water Reclamation Facility. The facility collects and treats municipal sewage and produces recycled water for reuse, maintaining a typical daily treatment flow of 7.8 MGD and a raw sewage treatment capacity of 11 MGD. The facility is slated for an ultimate expansion of 27 MGD to accommodate projected future sewage production from growth in the facility's service area. All EMWD facilities are currently determined to be in compliance with Regional Water Quality Control Board wastewater treatment requirements.

Wastewater production of the proposed project would be conveyed via on-site infrastructure improvements and the City's existing public sewer system facilities to the Hemet/San Jacinto Regional Water Reclamation Facility for treatment. The proposed development would include new on-site sewer infrastructure improvements including 12- to 30-inch sewer lines that would gravity flow via the proposed internal roadways to within a 30-inch trunk line in Ramona Boulevard and then continue to gravity flow toward the existing De Anza lift station, which would then travel through a force main to the Hemet/San Jacinto Regional Water Reclamation Facility for treatment (see *Figure 5.12-2, Master Sewer Plan*).

Based on an average sewage generation rate of 300 gallons per day per household, and 1,700 gallons per day per acre of commercial/mixed-use development, the proposed project's maximum of 1,329 residential units and 49 acres of commercial/mixed-use would generate 482,000 gallons per day of wastewater (based on factors from RBF Consulting, November 9, 2005). This wastewater would be treated by the Hemet/San Jacinto Regional Water Reclamation Facility. This assumes that the school site would be developed into single-family residential (the 313 dwelling units that would be built at the school site would generate more wastewater than a school and thus represents a worst case scenario). As described above, the Hemet/San Jacinto Regional Water Reclamation Facility currently treats up to 7.8 MGD and has a current capacity of 11 MGD and ultimate capacity of 27 MGD. The quantity of wastewater generated by the proposed project would not exceed the current sewage treatment capacity, assuming a worst-case scenario that no expansion of the facility takes place prior to project completion. Therefore, the proposed project's impacts related to availability of existing sewer treatment services would be less than significant.

The Specific Plan identifies the following conditions for development in the Specific Plan area:

- All water and sewer lines will be designed per the Eastern Municipal Water District's Water and Sewer System Planning and Design Criteria dated July 2, 2007, and September 1, 2006, respectively.
- The infrastructure system and phasing shall be designed and installed consistent with the City of San Jacinto Engineering Department requirements.
- The Eastern Municipal Water District will manage the development of infrastructure for the project area.
- Water and sewer facilities shall be installed in accordance with the requirements and specifications of the San Jacinto Engineering Department and the Riverside County Health Department.

The quantity of wastewater generated by the proposed development is not expected to exceed the sewage treatment capacity and the proposed Specific Plan policies require that a written agreement with EMWD be executed which states that the provision of services shall be available prior to the recordation of any tract maps. The Specific Plan policies further require that new sewer facilities are developed consistent with EMWD's planning and design criteria, and in accordance with the City Engineering Department. Therefore, all necessary facility infrastructure will be appropriately designed and constructed to serve the proposed development. Impacts related to sewer services would be less than significant.

Mitigation Measures

None.

Residual Impact/Level of Significance after Mitigation

The proposed Villages of San Jacinto Specific Plan includes development standards that would apply to all future build-out of the planning area which specifically includes development elements and/or policies and measures to ensure that adequate public facilities and services such as wastewater are provided in conjunction with build-out of the development. Therefore, impacts to wastewater systems would be less than significant.

5.12.7 Storm Drain Facilities

Existing Conditions

Stormwater runoff generated in the Specific Plan area currently drains primarily via sheet flow in a northerly direction toward the San Jacinto River. Existing drainage features on or near the project site consist of an open channel adjacent to the east property boundary that runs along Sanderson Avenue that conveys runoff north toward the San Jacinto River, and a depressed portion of land located at the northwest section of the project area which receives drainage across the site.

Significance Criteria

8. ***Would the project require or result in the construction of new storm water drainage facilities or expansion of existing facilities, the construction of which could cause significant environmental effects?***

Impacts

The project site generally drains in a northwesterly direction toward the San Jacinto River, primarily in a sheet flow pattern. The northerly portion of the project site is within the 100-year floodplain. The Drainage Plan provides 100-year flood protection for the project site for the interim and ultimate condition as described below.

Interim Condition

The interim condition assumes that surrounding areas remain undeveloped (such as in the existing condition), and the on-site development of the Villages of San Jacinto and corresponding infrastructure is independently functional. This includes the construction of two interim facilities and the reconstruction of an earthen roadway east of the De Anza Drive and

Sanderson Avenue intersection. These interim drainage facilities are required to control and convey the interim flow rates originating from the off-site area. Interim facilities include Culvert V, which will provide 100-year flood protection for Bridge Street; Culvert E, located north of the intersection of Sanderson Avenue and the Casa Loma Canal.

The Specific Plan identifies the following conditions for development of the Villages of San Jacinto:

- Drainage and flood control facilities and improvements shall be provided in accordance with City of San Jacinto and Riverside County Flood Control and Water Conservation District (RCFC & WCD) requirements.
- Project drainage facilities shall be publicly maintained. The City of San Jacinto will maintain storm drain systems that are equal to or less than 36-inches in diameter and all roadway culverts. RCFC & WCD will maintain all open channels and subsurface storm drains greater than 36-inches in diameter.
- RCFC & WCD will maintain lines and grades for all open channels. The City of San Jacinto will be required to maintain all landscape features and appurtenances. Additionally, the City will maintain turf reinforcement mats that will be used for stability of channel invert erosion.
- All projects proposing construction activities including: clearing, grading, or excavation that results in the disturbance of at least five acres total land area, or activity which is part of a larger common plan of development of five acres or greater, shall obtain the appropriate NPDES construction permit and pay the appropriate fees. All development within the Specific Plan boundaries shall be subject to future requirements adopted by the City to implement the NPDES program. Mitigation measures may include, but are not limited to: covered storage of all outside storage facilities; vegetated swales; monitoring programs; etc.

Section 5.8, Water Quality and Hydrology, indicates that improvements to the stormwater collection system and installation of a new on-site drainage system would be necessary to provide adequate storm drainage within the Villages of San Jacinto (see *Figure 5.8-2, On-Site Drainage Facilities*). The Specific Plan incorporates policies regarding control of stormwater runoff to reduce the overall quantity of stormwater and the Plan includes several specified components to improve drainage conditions and to ensure that drainage facilitates are provided to adequately control runoff from the site.

Mitigation Measures

See Mitigation Measures in *Section 5.8.5, Water Quality and Hydrology,* for measures related to provision of adequate storm drainage facilities.

Residual Impact/Level of Significance after Mitigation

The proposed Villages of San Jacinto Specific Plan includes development standards that would apply to all future build-out of the planning areas which specifically includes development elements and/or policies and measures to ensure that adequate public facilities and services such as storm drainage are provided in conjunction with build-out of the development. With implementation of the mitigation measures in *Section 5.8.5, Water Quality and Hydrology Mitigation Measures*, impacts to stormwater drainage systems would be less than significant.

5.12.8 Domestic Water Supply

The following discussion is based in part on the previously referenced Water Supply Assessment Report (December 15, 2004), and a letter from EMWD confirming their previous conclusions (May 11, 2009).

Existing Conditions

Domestic water supply is provided to the City of San Jacinto by the Eastern Municipal Water District (EMWD) which provides domestic and agricultural water supply, wastewater collection and treatment service, and recycled water in a 555 square mile service area from Moreno Valley to Temecula, and from Hemet and San Jacinto to Good Hope and Mead Valley. The EMWD serves a population of approximately 675,000 in Western Riverside County and generally provides approximately 110 million gallons of water per day for domestic and agricultural supplies and for other water agencies in the area (Eastern Municipal Water District, http://www.emwd.org/news/Insights/Insights4-09.pdf, accessed May 5, 2009). Water resources used to sustain the existing agricultural operations is provided primarily as recycled water by the EMWD, which is supplemented by groundwater produced by three on-site wells for which there are no restrictions on private use. Currently, irrigation for the turf farm operation consists of a combination of 95% reclaimed water and 5% groundwater.

The City is aware that some time has passed since the project's Water Supply Assessment (WSA) was adopted (December 15, 2004); therefore, the City has confirmed with EMWD that its WSA conclusions are still valid (letter dated May 11, 2009). The original WSA and confirmation letter are contained in Appendix K. The City has also taken into account other developments in water supply that may affect the project area and has provided this analysis below.

Delta Smelt: Kempthorne Case and New FWS Biological Opinion

On May 25, 2007, the United States District Court for the Eastern District of California ruled that the biological opinion prepared by the United States Fish and Wildlife Service (FWS) concerning the effects of long-term operations of the State Water Project (SWP) and the federal Central Valley Project (CVP) upon delta smelt was invalid under the federal Endangered Species Act. (Natural Resources Defense Council v. Kempthorne, et al., USDC Case No. 05-CV-1207-OWW.) On December 14, 2007, the court issued an Interim Remedial Order and Findings of Fact and Conclusions of Law requiring that the SWP and CVP operate according to certain specified criteria until a new biological opinion for the delta smelt was issued. Based on estimates prepared by the California Department of Water Resources (DWR), MWD estimated that for the year 2008, it would be subject to reductions in SWP supplies of up to a 30% as a result of the Kempthorne order, depending on prevailing hydrologic conditions and migratory status of the delta smelt.

On December 15, 2008, the FWS issued a new B.O. regarding the effects of CVP and SWP operations on delta smelt. According to preliminary information published DWR, which operates the SWP, the new B.O. will continue reductions in SWP and CVP exports from the Delta that were in effect since December 2007 under the federal court order in Kempthorne. DWR has estimated that under average water year conditions, the "most likely" result of the new B.O. is a 1% increase in the amount of available SWP supplies in comparison to the Kempthorne restrictions, although a worst-case scenario could result in a 13% decrease in available supplies. Under dry water year conditions, DWR states the "most likely" result of the new B.O. is the exact same type of potential restrictions as set forth in Kempthorne, although restrictions could possibly increase by 21% under a worst-case scenario. (See www.water.ca.gov/news/newsreleases/2008/121508swpimpacts.pdf.) As with the Kempthorne order, potential water supply restrictions under the new B.O. are dependent on various factors that cannot be predicted with a high degree of certainty, including hydrologic conditions, migratory and reproductive patterns of delta smelt, and other factors affecting delta smelt abundance in the Delta.

Due to a number of alleged scientific and other deficiencies in the new B.O., water agencies holding contracts to receive SWP supplies from DWR, among others, filed complaints in the Federal District Court for the Eastern District of California challenging the B.O. (See, *San Luis Delta-Mendota Water Authority et al. v. Salazar et al.*, Case No. 1:09-cv-407 (E.D. Cal., filed Mar. 3, 2009); *State Water Contractors v. Salazar, et al.*, Case No. 1:09-CV-422 (E.D. Cal., filed Mar. 4, 2009); *Coalition for a Sustainable Delta et al. v. United States Fish and Wildlife Service et al.*, Case No. 1:09-cv-480 (E.D. Cal., filed Mar. 12, 2009; amended complaint filed May 28, 2009); *Metropolitan Water District v. United States Fish and Wildlife Service*, Case No. 1:09-CV-631 (E.D. Cal., filed Apr. 8, 2009); and *Stewart & Jasper Orchards et al. v. United*

States Fish and Wildlife Service et al., Case No. 1:09-cv-892 (E.D. Cal., filed May 21, 2009)) These litigation matters challenging the validity of the new B.O. give rise to the additional possibility that SWP delivery reductions as set forth by the *Kempthorne* order could be put back in place pending final legal resolution of the new B.O. In light of these various factors, the degree to which SWP deliveries may be reduced under the new B.O. for delta smelt remains somewhat speculative at this time.

Salmon/Anadromous Species: Gutierrez Case and New NMFS Biological Opinion

SWP and CVP operations have also been challenged in a separate litigation matter, entitled *Pacific Coast Federation of Fishermen's Association / Institute for Fisheries Resources, et al. v. Gutierrez, et al*., (USDC Case No. 1:06-CV-00245-OWW). In October 2004, the National Marine Fisheries Service (NMFS) issued a "no jeopardy" determination and biological opinion (B.O.) analyzing impacts to threatened winter and spring-run salmon and steelhead trout in connection with SWP and CVP operations in the Delta through the year 2030. As with the *Kempthorne* case above, the project/action evaluated in the NMFS B.O. included current and future Delta pumping operations under the Operations and Criteria Plan (OCAP). In August 2005, several environmental plaintiff groups filed suit in federal court against NMFS and the Secretary of Commerce challenging the validity of the B.O. Several public agencies that hold contracts to receive water from the CVP and SWP intervened in the action. The plaintiffs later filed an amended complaint and thereafter the case was stayed for a period of time while the parties attempted to negotiate a settlement of the issues. The stay was later lifted and, in May 2007, the plaintiffs filed a motion for summary judgment to invalidate the B.O. without a trial. Similar to the situation discussed above in the *Kempthorne* case, NMFS and the Bureau of Reclamation decided, notwithstanding the outcome of the litigation, to reinitiate ESA Section 7 consultation regarding how the projects affect the protected anadromous species. Thus, the two agencies are now preparing the necessary documentation to produce a new B.O. A hearing on the summary judgment motions in the *Gutierrez* case was held on October 3, 2007, and on April 16, 2008, the Court issued its decision invalidating the NMFS B.O. for failing to comply with the federal ESA. As with *Kempthorne*, the Court did not vacate the B.O., meaning that CVP and SWP operations are authorized to continue pending the preparation of a new B.O. and any interim requirements the Court may impose. Proceedings were scheduled thereafter to determine whether interim restrictions such as those ordered in the *Kempthorne* case would be required pending the new B.O. On July 18, 2008, Judge Wanger issued Findings of Fact and Conclusions of Law which determined, among other things, that additional water supply restrictions beyond those required in *Kempthorne* (and now the new B.O.) are not required at this time. The Court again reached the same conclusion in a subsequent decision dated October 21, 2008.

On June 4, 2009, NMFS issued a new B.O. regarding the effects of CVP and SWP operations on protected salmon, steelhead, green sturgeon, and resident killer whales. According to draft

information published by DWR, NMFS has calculated that the B.O. has the potential to reduce combined CVP and SWP deliveries from the Delta by 5 to 7%, while DWR has initially estimated that average year reductions have the potential to range closer to 10%, in addition to restrictions imposed under the FWS B.O. for delta smelt. (See, http://www.water.ca.gov/news/newsreleases/2009/060409salmon.pdf.) As with the FWS B.O. for delta smelt and the Incidental Take Permit for longfin smelt, potential water supply restrictions under the NMFS B.O. are dependent on various factors that cannot be predicted with a high degree of certainty, including hydrologic conditions in the Delta region, migratory and reproductive patterns of protected anadromous fish, and other factors affecting the abundance of those species in the Delta. In June 2009, legal challenges were filed against the NMFS B.O. in the United States District Court for the Eastern District of California alleging, among other things, that the water supply restrictions set forth in the B.O. were established in violation of the federal Endangered Species, the federal Administrative Procedures Act, and other laws. (See, e.g., *San Luis & Delta Mendota Water Authority, et al. v. Locke, et al.*, Case No. 1:09-CV-01053-OWW-DLB; *Stockton East Water District v. United States National Oceanic and Atmospheric Administration, et al.*, Case No. 1:09-CV-01090-OWW-DLB.) The above-mentioned cases and other potential litigation that could be filed against the NMFS B.O. call into question whether the water supply restrictions in the B.O. can be imposed against the SWP. For these reasons, the degree to which SWP deliveries may be reduced under the new NMFS B.O. species remains speculative at this time.

Longfin Smelt: California Department of Fish and Game Incidental Take Permit

Another factor having the potential to affect the availability and reliability of SWP supplies is the March 4, 2009, decision by the California Fish and Game Commission (Commission) that listing the longfin smelt as a "threatened" species is warranted under the California Endangered Species Act (CESA). The longfin smelt is a small pelagic fish species, related to the delta smelt, whose habitat includes the Sacramento-San Joaquin Delta, among other areas along the West Coast. Under CESA, a threatened species is a native species or subspecies that, although not presently threatened with extinction, is likely to become an endangered species in the foreseeable future absent special protection and management efforts. CESA sets forth a general prohibition against the take of a threatened species except as otherwise authorized under CESA. One such authorization is provided by California Fish and Game Code section 2081, wherein the California Department of Fish and Game (DFG) may authorize the incidental taking of a threatened species in connection with an otherwise lawful activity through the issuance of a permit. On February 29, 2009, DFG issued Incidental Take Permit No. 2081-2009-001-03 (Permit) to DWR as the owner and operator of the SWP. The Permit applies to the ongoing and long-term operation of the SWP's facilities in the Delta, including Clifton Court Forebay, the John E. Skinner Fish Facility, the Harvey O. Banks Pumping Plant and the North Bay Aqueduct,

and authorizes DWR to incidentally take longfin smelt in connection with its operation of the SWP, provided the terms and conditions of the Permit are satisfied. The Permit imposes operating restrictions on the SWP facilities that are based in large part on the restrictions imposed on the SWP by the new B.O. issued by FWS for delta smelt (see above). As with the B.O. for delta smelt, potential water supply restrictions under the Permit are dependent on various factors that cannot be predicted with a high degree of certainty, including hydrologic conditions in the Delta region, migratory and reproductive patterns of longfin smelt, and other factors affecting longfin smelt abundance in the Delta. DWR has not indicated whether any particular reductions in SWP exports are likely to result from the Permit. Due to a number of alleged scientific and other deficiencies in the Permit, an organization of water agencies holding contracts to receive SWP supplies from DWR has filed a complaint in Sacramento County Superior Court challenging the Permit. (See, *State Water Contractors v. California Dept. of Fish and Game, et al*., Sac. Sup. Ct. Case No. 34-2009-80000203.) That case has brought DFG's ability to enforce the Permit into question. In light of the foregoing factors, potential reductions in SWP supplies resulting from DFG's Incidental Take Permit for longfin smelt remain speculative at this time.

SWP Supply Reliability: DWR 2007 SWP Delivery Reliability Report

While various factors can affect the availability and reliability of imported water supplies from the State Water Project (SWP), the likelihood of those supplies being available to MWD over the short, intermediate and long-term periods during normal, single-dry and multiple-dry year hydrologic cycles have been extensively analyzed and addressed by the California Department of Water Resources (DWR). In fact, commencing in 2003 and every two years thereafter, DWR prepares a SWP Delivery Reliability Report that is intended to assist local agencies, cities and counties in conducting water supply analyses to demonstrate whether their water supplies are sufficient for development projects subject to the CEQA review process. DWR's most recent 2007 Final SWP Delivery Reliability Report (DWR Reliability Report) was published in August 2008.

According to the DWR Reliability Report, the long-term average delivery of contractual amounts of SWP Table A supply is expected to range from 63% under current (2007) conditions to between 66 and 69% under future (2027) conditions. (DWR Reliability Report, pp. 44-45, 51-52, 55-56, 78.) Within that long-term average, SWP Table A deliveries can range from 6% (single dry year) to 90% of contractual amounts under current conditions (DWR Reliability Report, p. 44), and from 6 to 7% (single dry year) to 100% of contractual amounts under future conditions. (DWR reliability Report, pp. 51, 55-56.) The analyses provided in the DWR Reliability Report are based upon 82 years of historical records for rainfall and runoff that have been adjusted to reflect the current and future levels of development in the sources areas by analyzing land use patterns and projecting future land and water uses. (DWR Reliability Report, p. 20.) Of key

importance, the studies utilized in the DWR Reliability Report for current through future conditions (20-year projection) assume and account for current facility and institutional limitations facing the SWP, such as: water quality issues; fishery protections; export curtailments and other requirements under State Board Water Rights Decision 1641; the Vernalis Adaptive Management Plan (VAMP) as described in the 2004 Operations Criteria and Plan (OCAP); recent court-ordered Delta flow targets in Old and Middle Rivers to protect listed fish species; and potential effects of Delta levee failures and other seismic or flood events. (See, e.g., DWR Reliability Report, pp. 8, 16, 18-21, 27, 30, 32, 35, 37-39, Appendices A and B.)

In addition, DWR's long-term SWP delivery reliability analyses incorporate assumptions to account for potential supply shortfalls related to global climate change factors. (Ibid.) The DWR Reliability Report accounts for potential affects of future climate change on SWP deliveries through the year 2050 by examining four climate change scenarios: weak temperature warming and weak precipitation increase in California under model PCM; modest warming and modest drying under model PCM; modest warming and modest drying under model GFDL v. 2.0; and weak temperature warming and weak precipitation increase in California under model GFDL v. 2.0. (See DWR Reliability Report, pp. 1, 17, 27, 37-39, 43, Appendices A and B.) Thus, the effects of these institutional, administrative and court-ordered reductions in SWP exports, as well as the potential effects of long-term global climate change, have been extensively analyzed and accounted for in the supply forecasts set forth by DWR's 2007 Final SWP Delivery Reliability Report.

The 29 SWP Contractors and water agencies throughout California utilize the DWR Reliability Report in their water supply analyses, planning and reporting obligations. Indeed, both MWD's Regional UWMP and EMWD's 2005 UWMP acknowledge that SWP entitlements differ from actual SWP deliveries made available to SWP Contractors. (See, MWD Regional UWMP, pp. III-41 to III-50; EMWD 2005 UWMP, pp. 32-35.) SWP Contractors, including MWD, generally anticipate that the variability of SWP supplies may increase in the future as the Contractors request their maximum Table A amounts and as system-wide issues such as Delta exports are resolved. At the same time, however, SWP Contractors such as MWD who utilize groundwater basins to recharge portions of their SWP deliveries, as well as other exchange and transfer arrangements, can plan to receive long-term average deliveries of 66 to 69% of their SWP Table A allotments. (2007 DWR Reliability Report, pp. 39-40.) As indicated above, MWD has incorporated DWR's SWP reliability studies and analyzed several other key factors in developing its conservative estimate of long-term SWP deliveries. (MWD Regional UWMP, pp. III-41 to III-50.)

Drought Conditions: Regional Water Supply Planning, Statewide Drought Declarations, and Water Agency Responses

In its role as the supplemental water supplier to Southern California, MWD faces ongoing challenges in meeting the region's need for reliable, high-quality water supplies. (MWD Regional UWMP, p. II-1.) Increased environmental regulations and competition for water from outside the region have resulted in changes in delivery patterns and timing of availability of imported water supplies. (Id.) Because of competing needs and uses associated with these resources, and because of concerns related to regional water operations, MWD has undertaken a number of planning initiatives over the past ten years. MWD's Regional UWMP discusses and analyzes those efforts. Particularly important to MWD's mission is its coordinated approach to regional planning through the Integrated Resources Plan (IRP). The outcome of the IRP process was a "Preferred Resource Mix" which would ensure water supply reliability to MWD and its member agencies reliability. As part of the IRP, MWD has developed an overall reliability analysis in its computer-based model referred to as the IRPSIM, which evaluates the reliability of its water supplies, including supplies available from the SWP, the Colorado River, water transfers and exchanges, and other sources. (See, MWD Regional UWMP, pp. II-1 to II-15.) The IRPSIM is based on 70 years of historical hydrology (from 1922 to 1991) to allow it to estimate water surplus and shortage over a 20-year period and beyond. The model has allowed MWD to analyze the reliability of deliveries to its member agencies during worst-case single year and multiple year drought events. The results of MWD's modeling indicate that it can maintain reliable supplies to meet all member agencies' full-service demands without interruption throughout the 2005 to 2030 time period, including under drought conditions. (MWD Regional UWMP, pp. II-2/3, 11, 15.) Detailed analyses regarding MWD's supply projections are also set forth in Appendix A of MWD's Regional UWMP. As detailed in those analyses, MWD's overall supply and delivery reliability is based not just on Colorado River and SWP supplies, but also on conservation programs, groundwater storage programs, and water transfer and exchange programs.

A key component of MWD's water supply strategy is its Water Surplus and Drought Management Plan (WSDM). The purpose of the WSDM is to provide policy guidance and help manage regional water supplies to achieve the reliability goals of the IRP, where MWD seeks to maximize management of wet year supplies and minimize adverse impacts of water shortages to retail customers. Supporting principles of the WSDM include the encouragement of efficient water use and economical local resource programs, coordinated operations with member agencies to make as much surplus water as possible available for use in dry years, and the pursuit of innovative transfer and banking programs to secure more imported water for use in dry years. The WSDM contains the following considerations that would go into any equitable allocation of imported water: impact on retail customers and regional economy; investments in local

resources, including recycling and conservation; population growth; changes and/or losses in local supplies; participation in MWD's non-firm, interruptible programs; and investment in MWD facilities. The WSDM distinguishes between surpluses, shortages, severe shortages, and extreme shortages. Within the WSDM, each year MWD evaluates the level of supplies available and existing levels of water in storage to determine the appropriate management stage for that year. Each stage is associated with specific resource management actions designed to avoid extreme shortage scenarios to the maximum extent possible and minimize adverse impacts to retail customers if an extreme shortage occurs. The sequencing outlined in the WSDM reflects anticipated responses based on detailed modeling of MWD's existing and expected water supply resource mix. When MWD must make net withdrawals from storage to meet demands, it is considered to be in a shortage condition. Under most stages of shortage, MWD is still able to meet all end-use demands for water. For more severe shortage conditions, the WSDM shows that MWD will meet demands by withdrawing water from storage. Under worsening shortage conditions, MWD may undertake additional shortage management steps, including issuing public calls for extraordinary conservation, including the curtailment of Interim Agricultural Water Program deliveries in accordance with their discounted rates, exercising water transfer options, or open market water purchases. In an extreme shortage scenario, MWD may be required to implement a plan to allocate available supply fairly and efficiently among its full-service customers, which allocations are to be based on and enforced through rate surcharges where member agencies will be required to pay more for deliveries exceeding their respective allotments. (MWD RUWMP, pp. II-15/16.) The benefits of aggressive water conservation and public education efforts are also detailed in MWD's RUWMP. (See MWD 2005 RUWMP, pp. III-5 through III-21.)

On February 12, 2008, MWD adopted a Water Supply Allocation Plan (WSAP) as a component of its WSDM. As indicated above, the WSDM guides MWD's supply actions under both wet and dry conditions for achieving overall water supply reliability to its member agencies, including EMWD. The WSDM outlines various water supply conditions and corresponding actions MWD may undertake in response to serious water shortages. Under Condition 1, MWD issues a Water Supply Watch and encourages local agencies to implement voluntary dry-year conservation measures and utilize regional storage reserves. Under Condition 2, MWD issues a Water Supply Alert and calls for cities, counties, its member agencies and all other retail water providers to implement extraordinary conservation through drought ordinances and other measures to mitigate the use of storage reserves. Under Condition 3, MWD may implement its WSAP, which allocates available water supplies among member agencies based on factors such as impacts on retail customers, population and growth of particular member agencies, the availability of recycled water and other local supplies, conservation efforts, participation in MWD's interruptible water supply programs, and investment in MWD's facilities.

On June 4, 2008, the Governor of California proclaimed a statewide drought due to record-low rainfall in spring 2008 and court-ordered restrictions on Delta exports as discussed above. (Executive Order S-06-08.) Soon thereafter, the Governor proclaimed a state of drought emergency to exist within the Counties of Sacramento, San Joaquin, Stanislaus, Merced, Madera, Fresno, Kings, Tulare and Kern. (Proclamation dated June 12, 2008.) In response, MWD determined it was not necessary to implement its Water Supply Allocation Plan but, rather, on June 10, 2008 declared a Condition 2 water scenario and issued a Water Supply Alert, calling on local agencies and residents to take immediate steps for conserving water. On February 27, 2009, the Governor declared a statewide water supply emergency to combat California's third consecutive year of drought. (Proclamation dated February 27, 2009.) Relatively soon thereafter, on April 14, 2009, MWD's Board of Directors implemented its WSAP at a Regional Shortage Level 2 with the goal of reducing regional demand for wholesale water deliveries by 10%. This marks the first time MWD has implemented the WSAP since it was approved in February 2008 after a seven-month development process. The WSAP will go into effect on July 1, 2009, and has the potential to increase the cost of MWD water supplies to particular member agencies.

The WSAP outlines a three step process for determining each member agency's "allocation year" supply during a period of shortage. First, base period local supplies, wholesale demands and retail demands are calculated by averaging data compiled during a three-year base period which MWD established as 2004 through 2006. Base period local supplies are the average annual supplies generated by groundwater production, groundwater recovery, Los Angeles Aqueduct supply (for the Los Angeles Department of Water and Power), surface water production, and other imported supplies, but do not include non-potable recycled water production. Under the Plan, base period wholesale demand includes full-service water deliveries, seawater barrier, seasonal shift, and surface storage operating agreement demands. The base period retail demand is calculated by adding base period local supplies and wholesale demand. Base period demand figures are then used to estimate allocation year retail demands, local supplies and, ultimately, wholesale demands. Notably, total retail demands for the allocation period are calculated by adjusting the base period retail demands for growth. The growth adjustment is calculated using the estimated actual annual rate of population growth at the county level, as determined by the California Department of Finance. Similarly, allocation year local supplies are estimated using the base year local supplies, adding average in-lieu deliveries received during the base period and planned or scheduled increases in supply over the base year, and subtracting losses of local supply due to conditions such as hydrology or water quality. Allocation year wholesale demand, which serves as the basis of a member agency's ultimate allocation, is then calculated by subtracting allocation year local supplies from retail demands.

Extraordinary increases in production over the base year, defined as increases that occur solely due to the circumstances in that year such as purchasing water transfers or overproducing

groundwater yield, are not included in the allocation year local supplies during a Regional Shortage Level 1 or 2 and, therefore, do not reduce allocation year wholesale demand. In years where MWD declares a Regional Shortage Level 3 or above, only a fraction of an agency's extraordinary increase in production will be included in the allocation year local supplies which, in turn, will influence the agency's allocation year wholesale demand. In the final step, the allocation year wholesale demand is converted into a water supply allocation. Actual allocations will be adjusted with credits based upon an agency's past conservation efforts and relative dependence upon MWD water deliveries.

Allocations under the WSAP ultimately are achieved through a penalty rate structure enforced by MWD. If a member agency exceeds its allocation, penalty rates and charges will apply for water deliveries to the agency in excess of the allocation. MWD will track agency water use on a monthly basis and any applicable penalties are to be assessed at the end of an allocation year. Thus, member agencies are not subject to penalties on the basis of a high demand month but, rather, only if their total usage between July 1, 2009, and June 30, 2010, exceeds their total annual allocation. Penalties will be assessed through an ascending block structure that imposes a lower penalty for minor overuse and a higher penalty for higher exceedance of an agency's water supply allocation. The Plan provides for an allocation appeals process which may be used to address miscalculated base period supplies, unforeseen loss or gain in local supply, population growth rates, and other issues affecting an agency's allocation. As indicated above, MWD has implemented its WSAP at a Regional Shortage Level 2 with the goal of reducing wholesale demands within its service area, maintaining storage reserves and decreasing the risk of additional supply allocations in the future.

EMWD has taken numerous steps to prepare itself and its customers for the potential scenario where MWD may implement its WSAP. Through these steps, EMWD has been able to achieve extraordinary water conservation and demand management on an agency-wide basis such that MWD's recent allocation is not expected to result in an actual reduction in MWD water deliveries to EMWD. Rather, EMWD has sought to markedly change the manner in which water is used within its territory as a means of controlling the amount of additional imported supply it may need from MWD during the allocation period. The key components of EMWD's demand management strategy are discussed below.

EMWD recently adopted Ordinance No. 72.24 (February 4, 2009) establishing aggressive new requirements to achieve water use efficiency within its service territory. Indeed, Ordinance No. 72.24 states that the following water efficiency requirements shall apply to all existing and future customers: (a) refrain from hosing down driveways and other hard surfaces, except for health or sanitary reasons and then only by use of a hand-held bucket or similar container, a hand-held hose equipped with a positive self-closing water shut-off devise or a low-volume, high-pressure cleaning machine equipped to recycle any water used; (b) repair faucets, toilets, pipes and other

potential sources of water leaks; (c) irrigate landscape only between 9:00 p.m. and 6:00 a.m., although this provision does not apply when (i) manually watering during the establishment period of a new landscape, (ii) temperatures are predicted to fall below freezing, or (iii) for very short periods of time for the express purpose of adjusting or repairing an irrigation system; (d) refrain from watering or irrigating of any lawn, landscape or other vegetated area with potable water using a landscape irrigation system or watering device that is not continuously attended unless it is limited to no more than fifteen minutes watering per day per station, although this time limitation can be extended for (i) landscape irrigation systems that exclusively use very low flow drip irrigation systems when no emitter produces more than two gallons of water per hour, or (ii) whether based controllers or stream rotor sprinklers that meet a 70% efficiency, provided, however, that over-watering is not permitted in any case; (e) adjust and operate all landscape irrigation systems in a manner which will maximize irrigation efficiency and avoid over watering or watering of hardscape and the resulting runoff; (f) refrain from watering or irrigating any lawn, landscape or other vegetated area that causes or allows excessive water flow or runoff onto an adjoining sidewalk, driveway, street, alley, gutter or ditch; (g) do not use decorative fountains unless they are equipped with a recycling system; (h) do not allow water to run while washing vehicles, instead use a bucket or similar container and/or a handheld hose equipped with a positive self-closing water shut-off device to avoid run off into gutters, streets or alleys; (i) when installing new landscaping, plant low-water demand trees and plants and do not incorporate non-functional turf areas; and (j) refrain from water during rain. (EMWD Ordinance No. 72.24(1)(a)-(j).)

Another notable feature of EMWD's Ordinance No. 72.24 is its enforcement of the agency's tiered rate structure based on water budgets that apply to single-family, multi-family and landscape accounts that receive water from EMWD's domestic water system. Under Ordinance 72.24, four tiers are used to encourage efficient water use by customer groups and discourage the wasteful types of water uses identified above in Section 1 of the Ordinance. EMWD's Tier 1 Rate applies to an indoor water budget that is based on the gallons of water needed per person, per day. The Tier 2 Rate applies to an outdoor water budget that is based on square footage of landscape, actually daily ET, and a conservation factors, where (i) the default conservation factor for meters installed prior to September 1, 2008, is 1.0; (ii) the default conservation factor for meters installed after September 1, 2008, is 0.80 unless a lower ET adjustment factor is specified in the current State of California Model Water Efficiency Landscape Ordinance or the County of Riverside Water Efficient Landscape Requirements Ordinance; and (iii) the conservation factor can be adjusted up to 1.25 for functional areas at the discretion of EMWD. The Tier 3 Rate is applied to excessive water use that is measured as a percentage of Tier 1 and Tier 2 budgets, where a significantly higher rate can be charged for such excessive use. The Tier 4 Rate is applied to wasteful water use that exceed the Tier 3 limits. This rate is extraordinarily higher to discourage waste. (EMWD Ordinance 72.24(2)(a)-(d).) These tiered rates are more specifically

set forth in EMWD Resolution 3352. Ordinance 72.24 also establishes a strict penalty structure for water runoff. (EMWD Ordinance 72.24(3)(a)-(b).)

In a press release dated April 9, 2009, EMWD announced that its first tiered-rate bills had been distributed. In February and March, shadow bills accompanied regular bills to give customers an idea how their bills would have fared under the tiered structure. With EMWD's traditional rate structure, water rates were set according to a single commodity rate, regardless of the volume used. Under the new structure, each of EMWD's residential customers were provided with water budgets designed to give them the water they need for both indoor and outdoor uses. Indoor water budgets are based on the number of residents in the household, each using 60 gallons per day. The default single family residential household budget is based on three people, and multifamily residential is two. This comprises Tier 1. Outdoor water budgets are set according to the property's estimated irrigated area, based on County parcel data (lot size) and GIS information (house footprint, garage/carport area and driveway). The default for irrigated areas is generally set at 3,000 square feet, or up to 6,000 square feet for large landscapes. The outdoor portion comprises Tier 2. Together, the indoor and outdoor tiers form a household's water budget. Unlike other one-size-fits-all tiered rate structures, EMWD's includes allowances for larger households and for weather so greater outdoor irrigation is included in the budget during the summer. As stated in the press release, the purpose of the tiered rate structure is not to force people to go without water, but to eliminate excessive or wasteful use. The shadow bills also confirmed that 80% of EMWD's customers kept within their first two tiers, their water budgets. If tiered rates had been in effect at that time, those customers would have paid 18% less than their fixed commodity rates. Increased budgets can be approved for changes in the number of people in a household, larger landscaping areas, increased needs for large animals, child care or for medical requirements. Justification can also be made for allowing swimming pools to be refilled once every five years.

As an addition water saving measure, Ordinance No. 72.24 establishes stringent requirements for new landscape meters. First, EMWD requires a separate dedicated meter for landscape areas greater than or equal to 3,000 square feet. Second, the Ordinance provides that the efficient use of water should be considered in the design of any new landscape area, where EMWD will calculate an Annual Maximum Allowable Water Budget (AMAWB) for customers that request a new account using the following limitations: (i) the AMAWB will be calculated using the area's reference ET, the size of the landscaped area, and a conservation factor; (ii) for non-functional areas (landscape areas primarily used for aesthetic purposes, such as front yards, median strips, and parkways), a conservation factor of 0.80 will be used unless a lower factor for adjusting ET is specified in the current State of California Model Water Efficiency Landscape Ordinance or the County of Riverside Water Efficient Landscape Requirements Ordinance; (iii) for functional areas (landscape areas that serve as a surface for high traffic activities, such as playing a sport or

group gatherings), a conservation factor of 1.25 will be used at the discretion of EMWD; (iv) reference ET is given in inches per year, may vary by areas across EMWD, and will be established by EMWD; and (v) the AMAWB will be used to estimate outdoor water used, where the actual outdoor water budget applied to the account will be based on actual daily ET. Third, prior to the issuance of a landscape meter, the new customer shall calculate a water budget for each landscaped area, which budget cannot exceed the AMAWB limits calculated by EMWD. (EMWD Ordinance 72.24(4)(a)-(c).)

In addition to the foregoing, EMWD has also adopted a Water Shortage Contingency Plan ("WSCP") as part of its UWMP to address circumstances of drought, supply reductions, failure of water distribution systems or other emergency situations. (See, EMWD 2005 UWMP, Appendix D.) In fact, on March 5, 2009, EMWD adopted Ordinance No. 117.2 to amend its WSCP and more aggressively regulate the use of non-essential potable water during shortage and extreme shortage level conditions. Ordinance No. 117.2 expressly provides that its purposes is to help conserve available water supplies, protect the integrity of water supply infrastructure, and to help implement EMWD's contingency plan for times of drought and water supply shortages. (EMWD Ordinance 117.2, Section I.) Another stated purpose of the Ordinance is to achieve coordination and implementation of MWD's WSAP (see discussion above). (Id., Section III.) The water shortage contingency measures of Ordinance 117.2 apply to all persons, customers and properties within EMWD that utilize potable water and are implemented depending on the declared water supply condition as follows: Stage 1 exists when water deficiencies are predicted to or actually range between 0 and less than 5% of available supply and/or capacity; Stage 2 exists when water deficiencies are predicted to or actually range from 5% up to 10% of available supply and/or capacity; Stage 3 exists when water deficiencies are predicted to or actually range from 10% up to 15% of available supply and/or capacity; Stage 4 exists when water deficiencies are predicted to or actually range from 15 to 25% of available supply and/or capacity and storage is not recovering; Stage 5 exists when water deficiencies are predicted to or actually range from 25 to 35% of available supply and/or capacity and storage is not recovering; Stage 6 exists when water deficiencies are predicted to or actually range from 35 to 50% of available supply and/or capacity and storage is not recovering; Stage 7 exists when water deficiencies are predicted to or actually exceed 50% of available supply and/or capacity and storage is not recovering. (EMWD Ordinance 117.2, Section VII.)

Under any such stage, EMWD may employ any or all of the following public notification procedures: (a) notify the general public and influential local decision-makers about existing water supply conditions, actions to be taken, what customer involvement is intended to achieve, and how actions are to be implemented; (b) the public at large will be informed of the existing water supply conditions and what responses are needed, information that can be disseminated through billing inserts, special mailings, telephone contact, email, roadway signage, water

conservation booths, speaker engagements, community association meetings, newsletters, and other public education programming; (c) all available forms of media should be employed, including public service announcements on radio and television, as well as press coverage in local newspapers; and (d) posting all pertinent information on EMWD's website.

During a Stage 1 shortage, residential and potable landscape customers, as well as commercial, industrial and institutional ("CII") users, are encouraged to achieve a voluntary 10% reduction in water use by implementing the above mentioned requirements of EMWD's Water Use Efficiency Ordinance (Ordinance 72.24). A voluntary 5% reduction in water use is imposed on agricultural use. During Stage 2 conditions, all water users are required on a mandatory basis to comply with Ordinance 72.24 water saving measures to avoid the assessment of penalties. A mandatory 5% reduction in water use is imposed on agricultural use.

During Stage 3 conditions, household, potable landscape, and CII customers are required to achieve a 25% reduction in outdoor use and elimination of wasteful water use. In addition, the following restrictions apply: (1) watering or irrigating of lawn, landscape or other vegetated areas with sprinklers are subject to (i) watering only three days per week from June through August, (ii) two days per week in September, October and March through May, and (iii) one day per week November through February; (2) all leaks, breaks or other malfunctions in the water user's plumbing or distribution system must be repaired within 72 hours; (3) refrain from filling or re-filling of ornamental lakes or ponds; (4) refrain from using potable water to wash or clean a vehicle, including but not limited to, any automobile, truck, van, bus, motorcycle, boat or trailer, whether motorized or not; and (5) maintain existing water levels on swimming pools or outdoor spas. Agricultural customers are required to achieve a 10% reduction in water use.

During Stage 4 conditions, household, potable landscape, and CII customers are required to achieve a 50% reduction in outdoor water use and eliminate wasteful water use. In addition to the Stage 3 requirements set forth above, further restrictions can be used to avoid water use penalties, including: (1) watering or irrigating of lawn, landscape or other vegetated areas with sprinklers are subject to (i) watering only two days per week from June through August and (ii) one day per week from September through May. Agricultural customers are required to achieve a 15% reduction in water use. During Stage 5 conditions, all customers are required to achieve a 50% reduction in outdoor water use in addition to Stage 4 restrictions, and residential and potable landscape customers must eliminate water use in excess of 15% above their total indoor and outdoor water budgets. Agricultural customers are required to achieve a 25% reduction in water use. During Stage 6 conditions, all customers are required to achieve a 50% reduction in outdoor water use in addition to Stage 4 restrictions, and residential and potable landscape customers must eliminate water use in excess of their total indoor and outdoor water budgets. Agricultural customers are required to achieve a 35% reduction in water use. During Stage 7 conditions, residential and potable landscape customers are required to eliminate outdoor water

use except for purposes of health and safety and avoid exceeding indoor water budgets. CII customers are required to eliminate outdoor water use except for purposes of health and safety. Agricultural customers are required to achieve a 50% reduction in water use. (EMWD Ordinance 117.2, Sections IX–XI.)

As indicated by Ordinance No. 117.2, EMWD's implementation of water budgets and tier rate structures is intended to avoid the need for actually rationing community water supplies and preserve some latitude of choice with respect to how much potable water individual customers will use and how much customers are willing to pay for that water. (EMWD Ordinance 117.2, Section XII.) EMWD's approach and response to MWD's WSAP seeks to change the manner in which water is used within the agency, but it does not seek to physically curtail existing water deliveries or discourage new development. Recently, EMWD was declared to be in a Stage 1 water shortage condition where, as indicated above, all residential, potable landscape, and CII customers were encouraged to achieve a voluntary 10% reduction in water use by implementing the above mentioned requirements of EMWD's Water Use Efficiency Ordinance (Ordinance 72.24). On June 17, 2009, EMWD adopted Resolution No. 4918 to approve and authorize the declaration of Stage 2 conditions. The discussion above shows that during Stage 2 conditions, all water users are required on a mandatory basis to comply with Ordinance 72.24 water saving measures to avoid the assessment of penalties for wasteful uses of water.

Significance Criteria

9. ***Would the project have sufficient water supplies available to serve the project from existing entitlements and resources, or are new or expanded entitlements needed?***

Impacts

As previously indicated, EMWD provides an average of approximately 110 million gallons per day to consumers and other water agencies. Approximately 80% of the EMWD potable water supply consists of imported water from the Metropolitan Water District of Southern California (MWD), with additional water supply obtained from local groundwater basins and recycled water produced by five regional water reclamation facilities. Water supply for the City and surrounding region is predominantly obtained through MWD from the State Water Project which conveys most water resources from Northern California and is supplemented by water delivered via the Colorado River Aqueduct. Additionally, the EMWD has developed a 3,000 acre feet per year seasonal storage demonstration program in which untreated State Water Project water is purchased from MWD during years of surplus which is then used to recharge local groundwater basins later to be used in-lieu of imported water. The seasonal storage program results in economic and resource management benefits for both the EMWD and MWD.

As a member agency that receives 80% of its water supply from MWD, the EMWD relies on MWD's ability to provide adequate water supply to meet existing and future demands to asses EMWD's ability to meet the demands of its specific service area. The Water Supply Assessment Report prepared by EMWD for the proposed Villages of San Jacinto Specific Plan, dated December 15, 2004, indicates that in March 2003 MWD prepared a Report on MWD's Water Supplies which finds that with existing and planned water supplies MWD will be able to provide 100% of its member agencies' project demand through the year 2030, including during periods of repeated drought conditions. In addition to the findings for adequate water supply through 2030 of MWD's Report on MWD's Water Supplies, EMWD's Water Supply Assessment Report relies on additional findings of 100% water supply reliability through 2025 provided in MWD's Update to the Integrated Resources Plan, dated July 13, 2004, which considers various changed conditions of Southern California including projections of demographic and economic information obtained from regional planning agencies, the Southern California Association of Governments (SCAG) and San Diego Association of Governments (SANDAG).

Eastern Municipal Water District (EMWD) prepared and adopted an Urban Water Management Plan (UWMP) pursuant to the requirements of the California Urban Water Management Planning Act. The most recent UWMP was approved by the EMWD Board of Directors on December 21, 2005. The UWMP describes how EMWD will address urban water demands and the efficient use of urban water supplies for a 5-year period and includes a discussion of the District's existing and planned water demand management measures, and the methods by which proposed measures will be implemented during the plan period. The Water Supply Assessment Report prepared by EMWD for the proposed development evaluates the estimated project water demand in relation to anticipated date of full build-out of the development and whether the anticipated demand will remain within the limits of the UWMP for the District.

EMWD's water supply assessment for the proposed Villages of San Jacinto initially assumed a maximum residential build out of 2,022 units. The assessment, therefore, provides a conservative estimate of projected water demand for the proposed residential use that would not exceed 1,016 units (or 1,329 units which includes 313 units should the school site be developed with residential uses). Therefore, the projected water demand is a worst-case estimate that would occur. According to the Water Supply Assessment Report, the proposed development at full build-out of the Villages of San Jacinto would result in an average projected water demand of 1,620 acre-feet/year. The assessment assumes a 4-year build out period with an initial water demand of 405 acre-feet per year in 2007, and the total projected water demand of 1,620 acre-feet/year occurring in 2011. The Water Supply Assessment Report indicates that the total projected water demand for the proposed development would remain within the limits of the projected demand of the District's current UWMP.

The Water Supply Assessment Report further indicates that, because EMWD is depending on MWD to supply water to meet future demand, and MWD has projected growth in its service area using anticipated growth information provided by SCAG, EMWD has concluded that it will be able to meet the projected water demand of the proposed development as well as existing and future uses beyond 2025. In addition, EMWD has concluded that it will be able to meet future water demand for the next 20 years in the event of drought given that MWD does not place restrictions on imported water resources on member agencies, and given that MWD has found that, based on water demand determined by regional growth projections, it would be able to meet all member agencies' projected supplemental demand with existing and planned water supplies through 2030 even with the occurrence of repeat drought conditions. A letter from EMWD dated May 11, 2009, confirms their previous conclusions in the December 15, 2004, Water Supply Assessment Report. Therefore, potential impacts associated water supply insufficiencies are considered less than significant.

The existing City water facilities and infrastructure that would serve the Villages of San Jacinto include a 12-inch water line that occurs within the Sanderson Avenue right-of-way just south of the project site. Extension of a 16-inch water line along the Sanderson right-of-way to Ramona Boulevard is currently underway. These existing facilities have sufficient capacity to serve the maximum level of development permitted under the Specific Plan to the point of connection/s that would be required to distribute water throughout the Specific Plan area. A new water distribution system would connect to the Sanderson Avenue line via 12-inch pipelines and would distribute potable water throughout the development area primarily via 8-inch lines within the proposed internal street network (see *Figure 5.12-3, Master Water Plan*).

The Specific Plan identifies the following conditions for development in the Villages of San Jacinto:

- All water and sewer lines will be designed per the Eastern Municipal Water District's Water and Sewer System Planning and Design Criteria dated July 2, 2007, and September 1, 2006, respectively.
- The infrastructure system and phasing shall be designed and installed consistent with the City of San Jacinto Engineering Department requirements.
- The Eastern Municipal Water District will manage the development of infrastructure for the project area.
- Water and sewer facilities shall be installed in accordance with the requirements and specifications of the San Jacinto Engineering Department and the Riverside County Health Department.

Based on a worst case scenario assuming the proposed high school is built and a total of 1,016 homes are built (the school would result in higher water consumption than the 313 dwelling units that would replace the school), the total projected water demand is 853,640 gallons per day (gpd) for the proposed development (based on factors from RBF Consulting, November 9, 2005). This demand is expected to remain within the limits of the District's projected regional demand as outlined in the December 15, 2004, Water Supply Assessment for the project and affirmed by the May 11, 2009, letter from EMWD. The proposed Specific Plan policies require that a written agreement with EMWD be executed which states that the provision of services shall be available prior to the recordation of any tract maps. The Specific Plan policies further require that new water facility infrastructure be developed in accordance with the City Engineering Department and Riverside County Health Department, and development would be manage by EMWD. Therefore, all necessary infrastructure would be appropriately designed and constructed to serve the proposed development. Therefore, impacts related to water services would be less than significant.

Mitigation Measures

None.

Residual Impact/Level of Significance after Mitigation

The proposed Villages of San Jacinto Specific Plan includes development standards that would apply to all future build-out of the planning area which specifically includes development elements and/or policies and measures to ensure that adequate public facilities and services such as domestic water supply are provided in conjunction with build-out of the development. Therefore, impacts to domestic water supply systems and supplies would be less than significant.

5.12.9 Solid Waste and Recycling

Existing Conditions

CR&R Stanton Division provides solid waste and recycling management services for the City of San Jacinto. Solid waste disposal for the City of San Jacinto is directed to the Lamb Canyon Landfill which is owned and operated by the Riverside County Waste Management Department (RCWMD). The Landfill also services the Cities of Beaumont, Banning and Hemet, and the unincorporated areas of Pine Cove, Idyllwild, Cherry Valley, Cabazon, Homeland, Romoland and Winchester.

The Lamb Canyon Landfill is a Class III solid waste disposal site consisting of 1,088 acres of total landfill permit area. In December 2003, the California Integrated Waste Management Board approved a request by RCWMD for a Revised Full Solid Waste Facilities Permit and adopted a

Mitigated Negative Declaration to permit an increase in the overall capacity of the fill from 23,601,595 cubic yards to 34,292,000 cubic yards to accommodate the fill's projected design capacity for year 2023. In addition, the revised permit allowed for an increase in the amount of daily received waste from 1,900 tons per day to 3,000 tons per day to accommodate an anticipated five-year growth period of the service area (California Integrated Waste Management Board Resolution 2003-504, December 16–17, 2003).

The City is mandated by the California Integrated Waste Management Board (CIWMB) to divert 50% of its waste stream away from landfills through source reduction, recycling, and composting activities (AB939). Information obtained on the CIWMB website, indicates that the City of San Jacinto met the waste diversion standard with a 51% diversion rate as of the most recent available reporting year of 2006 (CIWMB, http://www.ciwmb.ca.gov, accessed on May 6, 2009).

Significance Criteria

10. ***Would the project be served by a landfill with sufficient permitted capacity to accommodate the project's solid waste disposal needs?***

11. ***Would the project comply with federal, state, and local statues and regulations related to solid waste?***

Impacts

Anticipated uses in the Villages of San Jacinto are typical of urban areas, and would not violate any federal, state, or local statutes or regulations related to solid waste.

As discussed previously, the Lamb Canyon Landfill, which is regulated by the CIWMB, approved a request by the RCWMD to permit an increase in the overall capacity of the fill from 23,601,595 cubic yards to 34,292,000 cubic yards to accommodate the fill's projected necessary design capacity to adequately serve residents of Riverside County through year 2023. The CIWMB also permitted an increase in the amount of daily received waste from 1,900 tons per day to 3,000 tons per day to accommodate an anticipated five-year growth period of the service area (California Integrated Waste Management Board Resolution 2003-504, December 16–17, 2003).

According to personnel of RCWMD, the department does not consider projected population and development growth rates of the service area to determine future waste generation. The fill capacity needed to meet future needs of the service area is due to various factors that affect the amount of solid waste that is actually received at the facility such as required waste diversion programs (AB 939) and construction/demolition materials associated with new development. Likewise, the County does not have a particular threshold to define a significant project-specific

impact to the solid waste system. The RCWMD, as an alternative, determines the landfill's estimated future capacity needs based on historical data that has documented an average 4% increase rate in waste disposal received by the fill (Ma, personal communication, December 3, 2004). Given the 4% growth rate of solid waste anticipated to be received by the landfill and the recent approved expansion of the fill to accommodate the anticipated growth rate for the service area through 2023, the proposed project would be served by a landfill with sufficient permitted capacity to accommodate the project's solid waste disposal needs.

Other factors to consider in evaluating the proposed project's potential impacts relative to waste generation include construction debris, recycling efforts, and potential hazardous waste generation. Because the project site is primarily vacant with the exception of a limited number of out buildings associated with current agricultural operations, development of the proposed project is not anticipated to result in an exceptionally large amount of construction waste generation that may otherwise result from large demolition activities of existing structures. Construction waste generation would be equivalent to that normally associated with new development and, therefore, would not substantially affect the landfill's capacity threshold to accommodate the service area. Therefore, potential impacts associated with solid waste generation and disposal is considered less than significant.

To ensure that the development of the proposed Specific Plan is maintained in compliance with the efforts of the City of San Jacinto to continue to meet the mandate of AB 393, a number of mitigation measures have been identified to facilitate appropriate waste generation minimization and recycling efforts, (see *Section 5.12.5, Mitigation Measures, Mitigation Measures 5.12-d through 5.12-f*).

Finally, CR&R Sanitary Service has indicated that it can serve future development in the Villages of San Jacinto area without the need to expand its Resource Recovery Center. Therefore, potential impacts associated with solid waste disposal services are considered less than significant.

Mitigation Measures

5.12-d Demolition and/or excess construction materials shall be separated on site for reuse/recycling or proper disposal (e.g., concrete asphalt). During grading and construction, separate bins for recycling of construction materials and brush shall be provided on site.

5.12-e Landscaping shall be designed and located to utilize drought tolerant species, minimize irrigation, and to reduce green waste generation.

5.12-f The developer shall develop and submit a Solid Waste Management Plan to be reviewed and approved by the City Public Works Solid Waste Division and Planning and Development, and shall include:

- Provision of space and/or bins for the storage of recyclable materials within the project site,
- Methods of waste collection,
- Information programs to future residents regarding disposal of hazardous wastes.

Residual Impact/Level of Significance after Mitigation

The proposed Villages of San Jacinto Specific Plan includes development standards that would apply to all future build-out of the planning area which specifically includes development elements and/or policies and measures to ensure that adequate solid waste facilities are provided in conjunction with build-out of the development. With implementation of the additional mitigation measures included above, impacts to solid waste facilities and providers would be less than significant.

5.13 HAZARDS/RISK OF UPSET

5.13.1 Introduction/Methodology

The focus of this section is to outline existing hazards present on site, regulatory guidelines related to hazard assessment and clean-up if necessary and how the proposed project may have an impact on identified hazards or create new hazards to the surrounding community once constructed.

The following analysis is based on the October 10, 2002, *Phase I Environmental Site Assessment Report* prepared by Gradient Engineers, Inc. This report is contained in *Appendix L* to this EIR. Methods used to survey and test the site are contained therein.

5.13.2 Existing Conditions

The Phase I Environmental Site Assessment reported one residential structure, one large warehouse, one small warehouse, a storage shed, two office trailers, three groundwater wells (one domestic, two irrigation), shelter areas for cows and equipment storage areas on site. A detention basin is located in the southwest corner of the site. As of a May 1, 2009, site visit, the only remaining structures were the abandoned residence which had deteriorated significantly from the time of the Phase I Environmental Site Assessment and shade structures associated with a former cattle operation (no cattle are currently present at the site). *Figure 5.13-1, Hazardous Materials Site Map* and *Figure 5.13-2, Hazardous Materials Detailed Site Map* show the location of each area described above.

On-Site Hazardous Material History

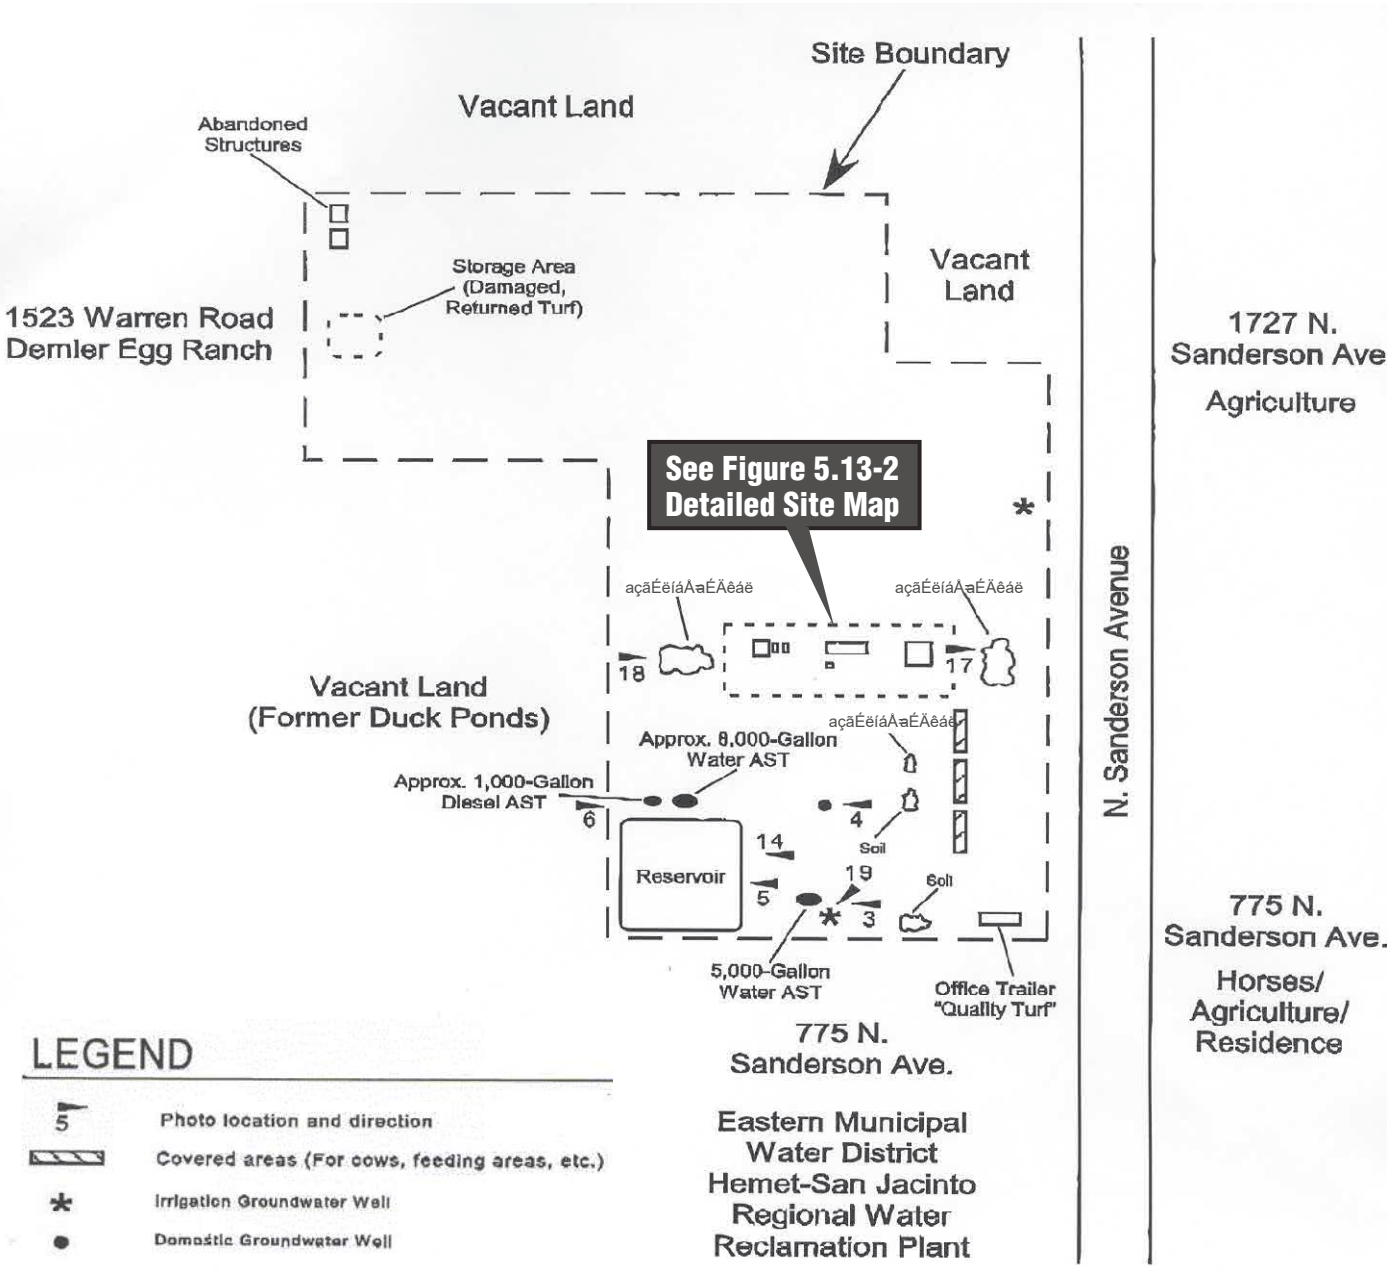
At the time of the survey for the Phase I Environmental Site Assessment, the project site was used as a sod farm and a heifer raising facility. Since 1949 (date of first available records), the property was used for agricultural purposes. In 1980, a heifer farm was established on site. By 1997, part of the property was converted into a sod farm. Quality Turf has leased a portion of the property for production of sod since 1997. Approximately twenty acres of the property has been leased for heifer raising activities since approximately 1978. However, the heifer raising facility was recently removed from the site, along with the manure which was converted to compost. The surrounding area consists of rural agricultural land uses. Agricultural land is located to the north and east while vacant land and a chicken ranch are located west of the project site. The San Jacinto Valley Regional Water Reclamation Facility is located to the south of the site.

One of the former land owners supplied the Phase I investigator with records detailing the removal of three Underground Storage Tanks (USTs). In 1999, two 1,000-gallon and one 10,000-gallon gasoline USTs were removed from the area southwest of the large warehouse. The

area where these tanks were formerly located was over-excavated and approximately 120 tons of contaminated soil transported off site for treatment.

Total petroleum hydrocarbons in the gas range (TPHg), benzene, toluene, ethylbenzene, xylenes and methyl tertiary butyl ether (MTBE). In October 2000, soil in this area of the property was retested for the above contaminants. In December 2000, a vapor extraction well was set up near the former tank locations to determine whether identifiable levels of petroleum hydrocarbons still existed. Contaminant level measurements of each sampling period are summarized in *Table 5.13-1, Historic UST Soil Contaminant Levels*.

Table 5.13-1
Historic UST Soil Contaminant Levels



Petroleum Hydrocarbon Tested	Testing Period		
	1999 (during UST removal)	October 2000	December 2000 (vapor measurements)
TPH-g	5,290 mg/kg	2,710 mg/kg	Significant levels not detected
Benzene	36.8 mg/kg	Not Measured	Significant levels not detected
Toluene	638 mg/kg	131 mg/kg	Significant levels not detected
Ethylbenzene	200 mg/kg	Not Measured	Significant levels not detected
Xylenes	352 mg/kg	486 mg/kg	Significant levels not detected
MTBE	377 mg/kg	169 mg/kg	Significant levels not detected

SOURCE: Gradient Engineers Inc, October 2002, p. 5.

Groundwater wells were also drilled to determine the depth of groundwater, and if appropriate, measure the level of contaminants. Groundwater was not encountered at 70 feet below ground surface and was expected to exist approximately 120 feet below ground surface. In December 2000, the Regional Water Quality Control Board recognized that the lack of identifiable vapors from the vapor test well indicated that remaining soil in the immediate area would not pose a threat to groundwater resources.

On December 26, 2001, the RWQCB issued a case closure summary and "no further action" letter for the previous underground storage tank issue. That said, the letter's case closure summary states "corrective action should be reviewed if the land use changes."

A review of aerial photographs indicates that a windmill was historically located at the northwest corner of the site.

Hazardous Materials Detailed Site Map

FIGURE 5.13-2

INTENTIONALLY LEFT BLANK

On-Site Hazardous Material Current Presence

As indicated on *Figure 5.13-1* and *5.13-2*, in addition to the structures present on the site, the site reconnaissance noted one 5,000-gallon, one 8,000-gallon, and one 15,000-gallon tank. One 1,500-gallon aboveground water storage tank was also observed. Three diesel fuel above ground storage tanks were also observed on site. Stained and discolored soil was observed beneath the diesel tanks.

Mr. Ralph Daily, manager of the Quality Turf Farm operation, provided a list of hazardous chemicals used for sod farm operations. These chemicals include diesel fuel, waste oil, drained used oil filters, pesticides and herbicides, oil and hydraulic fluids. Oily staining was observed on the concrete pads on the equipment associated with the groundwater irrigation well located east of the reservoir. The floor within the equipment shed was observed to be stained with an oily substance beneath the three 55-gallon drums. The ground beneath the floor was not accessible/observable during the Phase I site reconnaissance.

Visual evidence of Polychlorinated Biphyenyls (PCBs) was not observed on site during the Phase I Environmental Site Assessment visit, however, transformers were observed on poles throughout the property. Staining was not observed beneath these transformers.

Petroleum stained soil was observed beneath the diesel above ground storage tank located northwest of the reservoir, near the irrigation groundwater well located southeast of the reservoir, and on the floor of the equipment shed, beneath three oil containing 55-gallon drums.

Debris, including old equipment, water heaters, trash, etc., was observed in several piles throughout the site (see *Figure 5.13-1*, "cultural debris"). Several mounds of soil were observed on site. According to Mr. Daily, the soil piles were generated from on-site activities and were piled as such for storage.

Two septic systems are located on site. One is located near the residential structures, its exact location unknown and the other northeast of the larger warehouse. One existing reservoir is located on site. This reservoir contains reclaimed water from the nearby San Jacinto Valley Regional Water Reclamation Facility and is used for sod farm irrigation. Historic aerial photographs document previous reservoirs, however during the Phase I Environmental Site Assessment, these reservoirs were no longer located on the property.

Three groundwater wells are located on site. One is used for domestic water while the other two are used for irrigation. According to Mr. Daily, the depth of the domestic water well is approximately 150 feet below ground surface while the irrigation wells range from 300 to 400 feet below ground surface. Oil, gas production or groundwater monitoring wells were not

observed or reported at or near the site. The vapor extraction well noted above was abandoned in 2002.

An asbestos building material and lead-based paint assessments were not performed for the project site.

Off-Site Hazardous Material History/Presence

A search on the First Search Report Environmental Database Report System was conducted to determine presence of any nearby hazards outside of the property limit boundaries. The following databases were searched: Federal National Priorities List (NPL), Federal Comprehensive Environmental Response Compensation and Liability Information System (CERCLIS), Federal Resource Conservation Recovery Act (RCRA) Notifiers List, Emergency Response Notification System (ERNS), Toxic Release Inventory System (TRIS), Department of Toxic Substances Control Sites (CALSITES), Solid Waste Landfill Facilities, Underground Storage Tank (UST) sites, Leaking Underground Storage Tank (LUST) sites, and unmapped listings. A description of each list's content is included in Section 4.1.2 of the Phase I Environmental Site Assessment included as *Appendix L* to this EIR.

The above regulatory database lists were reviewed for cases pertaining to leaking USTs and ASTs, hazardous waste sites and abandoned sites within the specified radii of standards established by the American Society for Testing and Materials (ASTM). The First Search Report did not indicate the presence of any facilities that appear to represent a potential source of migration of hazardous substances to soil or groundwater beneath the proposed project site.

The site's location on several local databases was also searched. The following local databases were searched: Riverside County Department of Environmental Health, Riverside County Fire Department, California Regional Water Quality Control Board (Santa Ana Region), Department of Toxic Substances Control and South Coast Air Quality Management District.

In 1990, the State of California conducted a radon survey across the state. The results of the survey indicate that the testing area within which Riverside County is located, is below the U.S. EPA radon action level.

5.13.3 Significance Criteria

Based on the criteria identified in Appendix G of the CEQA Guidelines, the proposed project would have a significant impact on hazards/risk of upset if it:

1. Create a significant hazard to the public or the environment through the routine transport, use or disposal of hazardous materials?

2. Create a significant hazard to the public or the environment through reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment?
3. Emit hazardous emissions or handle hazardous or acutely hazardous materials, substances or waste within one-quarter mile of an existing or proposed school?
4. Be located on a site which is included on a list of hazardous materials sites compiled pursuant to Government Code Section 65962.5 and, as a result, would it create a significant hazard to the public or the environment?
5. For a project located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, would the project result in a safety hazard for people residing or working in the project area?
6. For a project within the vicinity of a private airstrip, would the project result in a safety hazard for people residing or working in the project area?
7. Impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan?
8. Expose people or structures to a significant risk of loss, injury or death involving wildland fires, including where wildlands are adjacent to urbanized areas or where residences are intermixed with wildlands?

5.13.4 Impacts

Would the project create a significant hazard to the public or the environment through the routine transport, use, or disposal of hazardous materials?

Construction of the proposed project would involve the transport of gasoline and other potentially hazardous material to the project site for the sole purpose of equipment fueling. However, once project construction is complete, the transport, use or disposal of hazardous materials would be limited to household cleaning products, landscaping chemicals and fertilizers, and other substances associated with residential and recreation (park) uses and such items that may be available for resale in future commercial uses. Therefore, significant impacts are not anticipated to occur.

Would the project create a significant hazard to the public or environment through reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment?

Hazardous materials potentially found at the site are related to the historic use of fertilizers, herbicides and pesticides; potential methane production related to former cattle feed lot; petroleum residues; household debris; and asbestos in older buildings.

Due to the historic use of approximately 20 acres of the property as a heifer raising farm, the presence of manure may result in significant environmental impacts related to methane gas exposure. In order to reduce potential impacts to a level below significance, mitigation is provided (see *Section 5.13.5, Mitigation Measures, Mitigation Measure 5.13-a*).

As indicated in *Section 5.13.3*, the vapor extraction test well installed in December 2000 to monitor residual contaminants left from the previous underground storage tanks did not indicate a significant presence of petroleum hydrocarbons in the soil. Any remnant petroleum hydrocarbons remaining in the soil are not extensive enough to pose a threat to nearby groundwater. The issuance of the Regional Water Quality Control Board's "no further action" letter indicates that hazardous materials previously present on the site have been removed to a level that no longer poses a threat to the environment. Therefore, while the project site contains historic environmental hazards, these hazards have been removed and would no longer pose significant health risks to the public or environment. That said, the Regional Water Quality Control Board and Riverside County Department of Health Services will be notified of the change in use and regulatory procedures may be required to ensure that the site is safe for reuse (see *Section 5.13.5, Mitigation Measures, Mitigation Measure 5.13-b*).

Historic windmills were often powered by diesel fuel. The diesel fuel source was often stored in underground storage tanks. During the Phase I Site Assessment, diesel storage tanks were not noted nor did they appear on federal or state databases within the vicinity of the old windmill. That said, often underground storage tanks are unreported and therefore could be discovered during grading. If an underground storage tank or stained soil or soil with a petroleum hydrocarbon odor is uncovered, a potentially significant impact could occur. In order to reduce potential impacts related to undocumented underground storage tanks or contaminated soil, mitigation is provided (see *Section 5.13.5, Mitigation Measures, Mitigation Measure 5.13-c*).

According to Mr. Daily, when the sod is harvested, a portion of the soil is harvested along with the sod. Pesticides and herbicides are normally found in the upper one to two feet of soil, therefore, with the continual harvesting of the sod, it is unlikely that significant pesticide, herbicide or fertilizer residue remains in the soil or represent an environmental concern to development of the site. Early pesticide and/or herbicide use would have degraded into the soil

over the years and would also not result in an existing environmental concern. Furthermore, the types of pesticides/herbicides used for current sod operations are not an environmental concern.

Visual evidence of Polychlorinated Biphyenyls (PCBs) was not observed on site during the Phase I Environmental Site Assessment visit, however, transformers were observed on poles throughout the property. Staining was not observed beneath these transformers. Therefore contamination from transformer activity on site is not expected. Therefore, a less than significant impact would occur.

Petroleum stained soil was observed beneath the diesel above ground storage tank located northwest of the reservoir, near the irrigation groundwater well located southwest of the reservoir and on the floor of the equipment shed, beneath three oil containing 55-gallon drums. In order to avoid potential exposure of the environment or the public to potential contaminants in these areas, mitigation is provided (see *Section 5.13.5, Mitigation Measures, Mitigation Measure 5.13-d*).

Debris, including old equipment, water heaters, trash, etc., was observed in several piles throughout the site. In order to avoid potential significant impacts related to improper disposal of debris piles, mitigation is provided (see *Section 5.13.5, Mitigation Measures, Mitigation Measure 5.13-e*).

Two septic systems are located on site. In order to reduce potential impacts related to biohazard contamination as a result of septic tank residue, mitigation is provided (see *Section 5.13.5, Mitigation Measures, Mitigation Measure 5.13-f*).

Once the project is developed, domestic water will come from imported water sources from Eastern Municipal Water District rather than on-site groundwater supplies. In order to close the three on-site groundwater wells, and any additional wells that are discovered during site development, without resulting in potentially significant impacts to the environment, namely local groundwater sources, mitigation is provided (see *Section 5.13.5, Mitigation Measures, Mitigation Measure 5.13-g*).

In 1990, the State of California conducted a radon survey across the state. The results of the survey indicate that the testing area within which Riverside County is located, is below the U.S. EPA radon action level. Therefore, the potential for elevated radon levels at the site appear to be low.

Due to the age of many on-site buildings, the potential for asbestos-laden material exists on site. In order to reduce any impacts related to asbestos hazards, mitigation is provided (see *Section 5.13.5, Mitigation Measures, Mitigation Measure 5.13-h*).

Due to the age of many on-site buildings, the potential for lead-based paint materials exists on site. In order to reduce any impacts related to lead-based paint hazards, mitigation is provided (see *Section 5.13.5, Mitigation Measures, Mitigation Measure 5.13-i*).

Would the project emit hazardous emissions or handle hazardous or acutely hazardous materials, substances, or waste within one-quarter mile of an existing or proposed school?

There are no existing schools within one-quarter mile of the site, but the project includes a planning area for a potential high school. However, the project does not include any proposed land uses which would result in the release or handling of hazardous or acutely hazardous materials.

Would the project be located on a site which is included on a list of hazardous materials sites compiled pursuant to Government Code Section 65962.5 and, as a result, would it create a significant hazard to the public or environment?

As indicated in the second impact response above, a number of hazardous conditions may exist on the project site due to historical uses. All of these potential impacts have been reduced to a less than significant level with recommended mitigation. As discussed above under Section 5.13.2, a search of federal databases was conducted to determine presence of any nearby hazards outside of the property limit boundaries which did not indicate the presence of any facilities that appear to represent a potential source of migration of hazardous substances to soil or groundwater beneath the proposed project site.

For a project within an airport land use plan, or where such a plan has not been adopted, within two miles of a public airport or public use airport, would the project result in a safety hazard for people residing or working in the project area? For a project within the vicinity of a private airstrip, would the project result in a safety hazard for people residing or working in the project area?

The project would not subject users to safety hazards associated with public or private airports, since no airports are located within two miles of the project site.

Would the project impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan?

In order to reduce the potential for construction traffic conflicts which may include emergency evacuation plans, a traffic control plan shall be developed to the satisfaction of the City Engineer, as a standard condition of the project.

Would the project expose people or structures to a significant risk of loss, injury or death involving wildland fires, including where wildlands are adjacent to urbanized areas or where residences are intermixed with wildlands?

The project site is not located adjacent to wildland areas. The project site is surrounded by mainly by agricultural land uses, scattered residential and the water reclamation facility located to the south. As such, the project would not expose people or structures to a significant risk of loss, injury or death involving wildland fires.

5.13.5 Mitigation Measures

5.13-a In order to ensure that methane hazards do not exist on the 20 acre portion of the site formerly used for heifer raising activities, the Riverside County's Methane Investigation Protocol shall be followed during and after site preparation. After grading of the 20 acres, methane gas sampling and any associated mitigation mechanism installation shall occur in accordance with the most recent Riverside County Department of Environmental Health protocols.

5.13-b The Regional Water Quality Control Board and Riverside County Department of Health Services shall be notified of potential site reuse in accordance with the December 26, 2001 "no further action" letter provided for the remediated leaking underground storage tanks. These agencies may require additional processing or testing depending on the ultimate reuse of the specific area contaminated. In order to ensure that regulatory compliance has been met, on-site soils shall be tested prior to grading to determine the presence of contaminants. Testing results will help determine if permissible levels of contaminants have been exceeded. If levels have been exceeded, impacted soils shall be remediated in accordance with Riverside County Department of Health Service protocol.

5.13-c The former windmill site shall be flagged prior to site grading. During site grading near the former windmill site, a qualified hazardous materials specialist shall monitor grading activities. If an underground storage tank or petroleum hydrocarbon odor-laden soil is uncovered near the old windmill site, grading and site work shall cease and the Regional Water Quality Control Board and Riverside County Department of Health Services notified. A remediation plan shall be developed to ensure that all contaminated soil and structures are removed, handled and disposed of in accordance with existing state and local regulations. Sampling in the area of impacted soils shall continue until contaminant levels reach an acceptable risk.

5.13-d In order to mitigate for potential hazards associated with petroleum stained soil beneath diesel storage tanks and on the floor of the equipment shed beneath 55-gallon oil storing drums, collection of surface and near surface samples by a qualified hazardous materials

specialist must occur. Following removal of the equipment shed, observations will be made for any stained soil beneath the shed. If stained areas are observed, surface and near surface samples shall be collected. Testing for contaminant levels must occur and an assessment of significance under state and local hazardous material regulations must follow. Once contaminant levels are determined, the Regional Water Quality Control Board and Riverside County Department of Environmental Health must be contacted to determine the proper mitigation method prior to site redevelopment. Any soil and other materials contaminated with hazardous materials may be considered hazardous waste and therefore must be disposed of in accordance with federal, state and local regulations.

5.13-e During removal of debris piles, a qualified hazardous materials specialist shall be on site. The hazardous materials specialist will conduct a site assessment of debris pile content and direct disposal accordingly. All waste products will be disposed of in accordance with state and local laws.

5.13-f In order to mitigate for potential hazards associated with existing septic tanks on site, the construction contractor shall remove the tanks and residue material in accordance with Riverside County Department of Environmental Health protocol. The project applicant will then be required to provide proof of septic tank removal to the City prior to issuance of building permits.

5.13-g In order to prevent groundwater contamination, the three on-site groundwater wells and vapor monitoring well, and any additional wells uncovered during site development, shall be abandoned and decommissioned in accordance with Regional Water Quality Control Board and Riverside County Department of Health protocols. The project applicant will be required to provide proof of well decommissioning to the City prior to issuance of building permits.

5.13-h Prior to demolition of on-site buildings, an asbestos survey shall be performed by a certified asbestos abatement contractor. Findings in the survey shall be used to determine what precautions shall be taken during demolition activities. If asbestos is present, removal shall occur in accordance with Riverside County Department of Environmental Health protocol.

5.13-i All building material suspected to contain lead-based paint shall be tested prior to demolition. If lead-based paints are present, removal shall occur in accordance with Riverside County Department of Environmental Health protocol.

5.13.6 Residual Impacts/Level of Significance after Mitigation

Incorporation of the proposed mitigation measures would reduce any potential impacts to a level below significance.

SECTION 6.0
CUMULATIVE IMPACTS

6.1 INTRODUCTION/PURPOSE

In many cases, the impact of a single project may not be significant, but when combined with other projects, the "cumulative" impact may be significant. Section 15355 of the CEQA Guidelines defines "cumulative impacts" as two or more individual effects which, when considered together, are considerable or which compound or increase other environmental impacts." CEQA Guidelines Section 15130(b) states that "the discussion [of cumulative impacts] need not provide as great of detail as is provided of the effects attributable to the project alone." Section 15130(b) further states that a cumulative impacts discussion should be guided by the standards of practicality and reasonableness.

Cumulative impacts can occur from the interactive effects of a single project. For example, the combination of noise and dust generated during construction activities can be additive and can have a greater impact than either noise or dust alone. However, substantial cumulative impacts more often result from the combined effect of past, present and future projects that are located in proximity to the project under review. For example, the wastewater treatment demand generated by a project may not be significant when analyzed alone, however, when analyzed in combination with the wastewater demands of approved or proposed projects, the wastewater demands may exceed the resource capabilities of the service agency, resulting in a significant cumulative impact. Therefore, it is important for a cumulative impacts analysis to be viewed over time and in conjunction with other related past, present and reasonably foreseeable future developments which may have impacts that might compound or interrelate with those of the project under review.

6.2 CUMULATIVE FORECASTING METHODOLOGY

Section 15130 (b)(1)(A) of the CEQA Guidelines allows for the preparation of a list of past, present, and reasonably anticipated future project as a viable method of determining cumulative impacts. This discussion utilizes that approach: an initial list and description of all related projects followed by a discussion of the effects that the proposed project may have on each environmental category of concern, such as traffic, noise, or biology. Consistent with CEQA, this discussion is guided by the standards of practicality and reasonableness.

6.3 LIST OF RELATED PROJECTS

This section of the analysis provides a list of past, present, and reasonably foreseeable future projects. Several development proposals, City projects and public infrastructure projects have been submitted for consideration or have been recently approved by local government agencies

in proximity to the proposed project that together with the proposed project would result in an increase in urban development/construction-related environmental impacts. To analyze cumulative impacts, the western San Jacinto area will serve as the study area which includes land along the western city limits to the general State Street area to the east (some projects east of State Street are included consistent with the traffic analysis as discussed below). Esplanade Avenue makes up the southern boundary and the northern city limits and areas adjacent to Ramona Expressway the northern boundary. The list of cumulative projects was compiled throughout the EIR preparation process (late 2004 to spring 2009). The existing list was updated in April 2009 in association with development of the most recent traffic report for the project (*Villages of San Jacinto Traffic Impact Analysis*, Urban Crossroads, April 24, 2009, included in *Appendix H* of this report). This list is similar to those contained in *Table 5.9-4, 2023 Cumulative Project Trip Generation*. However, some of the smaller projects and public infrastructure projects were not included in the traffic report. However, these projects have been included in the table below.

General project description information for each cumulatively considerable project is contained in *Table 6.0-1, Villages of San Jacinto Cumulative Projects List*. The location of each project is depicted on *Figure 6.0-1, Cumulative Projects.*

Table 6.0-1

Villages of San Jacinto EIR

Cumulative Projects

FIGURE 6.0-1

INTENTIONALLY LEFT BLANK

6.4 IMPACTS TO ENVIRONMENTAL FACTORS

Land Use Planning and Zoning

This project, when combined with the others planned within the western portion of the City of San Jacinto, would result in a large increase in suburban land uses adjacent to existing agricultural land uses. However, this area will continue to convert to urban-type uses consistent with the General Plan, which would ultimately alleviate potential land use conflicts between existing agricultural uses and planned development. Therefore, the cumulative impact of land uses would not be incompatible with the surrounding mixture of land uses planned within the area. This portion of the City, when combined with the other projects outlined in *Table 6.0-1* would be consistent with the City of San Jacinto General Plan adopted on May 4, 2006, and the latest General Plan Land Use Map approved in February 2009 which reflects the future direction of land use form envisioned for this portion of the City. Analysis of individual projects as they are submitted to the City will ensure compatibility with applicable plans and policies.

Agricultural Resources

The proposed project would result in significant, unmitigable impacts to agricultural resources. When combined with the other surrounding projects which also involve conversion of agricultural resources into suburban uses, a significant decrease in agricultural land use within the City of San Jacinto would occur. In summary, the project, when combined with many of the cumulatively considerable projects listed in *Table 6.0-1*, would contribute to a significant, unmitigable cumulative impact to agricultural resources. As discussed in *Section 5.3, Agricultural Resources*, the City's General Plan EIR (January 2006) discusses a number of reasons mitigation for loss of agriculture is infeasible. Rising land costs to replace agricultural lands, increasing water costs, labor costs, urbanization and environmental regulations all contribute to ongoing conversion of farmland. Without property owner cooperation and substantial financial incentives, it is infeasible to provide permanent on or off-site mitigation to replace converted farmland.

Landform Alteration and Aesthetics

The proposed project will contribute to the gradual change in visual character of the Sanderson Avenue corridor and the western San Jacinto Valley. The project represents a transition from a rural and agricultural area to a landscape that can be characterized as suburban in nature. These visual changes will be most evident from Sanderson Avenue and other major roadways which have sweeping views of the project site. However, neither the project, nor cumulative development would represent a substantial degradation in visual quality of designated scenic resources such as the Lakeview Mountains or other unique topographic features or result in a substantial impediment to scenic views provided such development is consistent with planned

land uses in the vicinity of the project and with General Plan development and design guidelines. Therefore, cumulative impacts related to visual resources are not anticipated.

Biological Resources

Although the project will result in minimal direct impacts to biological resources, development of this project, combined with the others described above would contribute to the increase in human presence within the western San Jacinto Valley. Continued development within the western areas of the City would extend urban land uses into vacant areas characterized by natural and/or agriculturally utilized habitats that are used by the region's sensitive plant and wildlife species. That said, the project is consistent with the Western Riverside County MSHCP, which is, in effect, an attempt at a cumulative/big-picture approach to mitigating the impacts of increased urban development on the region's plant and wildlife species. Analysis of individual projects for consistency with the MSHCP will provide mitigation for biological resources, including payment of development fees to support implementation of the MSHCP and will reduce cumulative impacts to less-than-significant levels.

Cultural Resources

Any potentially significant cultural resource impacts associated with development on surrounding projects would be site-specific and can be mitigated on a project-by-project basis. Therefore, since individual projects would be fully mitigated, residual cumulative impacts to the region would not occur. Therefore, the cumulative effect when considering all these projects combined would result in a less than significant cumulative impact to cultural resources.

Geology/Soils

Most geology and soil hazards associated with development on surrounding projects would be site-specific and can be mitigated on a project-by-project basis. Such hazards include exposure of people or structures to rupture of an earthquake fault, liquefaction, landslides, unstable geologic units, and expansive soils. The individual project mitigation for these hazards will ensure that there are no residual cumulative impacts. There is potential for a cumulative impact of all related projects on soil erosion in the project area. However, the City of San Jacinto requires construction Best Management Practices which include soil stabilization and erosion control techniques. Therefore, no significant residual cumulative impacts related to geology and soils resources would occur.

Paleontological Resources

As with other cultural resources, all significant paleontological resources associated with this and other projects will be mitigated on a project-by-project basis. Because each project would be

required to fully mitigate for any potential paleontological resources, residual cumulative impacts to regional paleontological resources would not occur.

Water Quality and Hydrology

Runoff from project construction areas and parking lot and landscape irrigation systems will contribute to the incremental increase in urban runoff to the San Jacinto River system. However, compliance with Regional Water Quality Control Board requirements of attenuating all project drainage on site to ensure that post construction discharge does not exceed existing quantities, ensures that both a project-specific and cumulative increase to regional drainage (and therefore potential flooding of downstream systems) is avoided. Further, by ensuring that project mitigation measures (which are in the form of construction, design, and operational best management practices) are incorporated, any runoff does not result in a localized water quality contamination issue. Further, because all surrounding projects are regulated under the same City and Regional Water Quality Control Board standards, they too will be required to attenuate all drainage on site (to maintain pre development flow quantities) and incorporate water quality design features to prevent cumulative impacts to local drainage systems or water quality.

Further, although the City does not have control over it, a regional drainage master plan, referred to as the San Jacinto Master Drainage Plan (MDP) is being planned to provide a regional stormwater conveyance system for the western San Jacinto area. This regional drainage system will also help appropriately convey and/or attenuate drainage generated by future western San Jacinto urban development. This future facility would help with cumulative drainage issues in this region. However, as indicated above, the absence of this facility is not resulting in a project-specific or cumulative impact to drainage because all existing projects in the planning process are being required to attenuate all flows on site in the interim basis.

Transportation, Circulation and Access

Implementation of the mitigation measures included in *Section 5.9.5, Mitigation Measures*, would ensure that regional traffic conditions do not dip below an acceptable LOS (LOS D) for existing plus project conditions. However, without completion of the Mid County Parkway and SR-79 projects, the project would contribute to a cumulative significant impact. Mitigation proposed for this significant cumulative impact is infeasible due to exceedance of General Plan roadway criteria (i.e., triple left turn lanes at Warren Road and Ramona Expressway, and extensive improvements required along Sanderson Avenue) and the uncertainty of obtaining adequate right-of-way for such measures. Therefore, because the City can not guarantee that regional improvements would be implemented prior to completion of the project, a significant unmitigable cumulative traffic impact would occur. That said, it should be noted that the unacceptable LOS conditions would occur with or without the project under cumulative

conditions in the absence of the Mid County Parkway and SR-79 improvements. Significant cumulative impacts can not be mitigated; therefore, significant cumulative impacts would occur as a result of the proposed project and many other cumulatively considerable projects depicted on *Figure 6.0-1*.

Air Quality

Regional Air Quality

Implementation of the project would result in short-term impacts to air quality associated with construction and long-term impacts associated with increased vehicle traffic to and from the site as well as energy use. Buildout of the proposed project would occur from 2011 to 2033, with the nonresidential land uses constructed during the last 10 years. As the proposed construction would occur over a 22-year time period, there is the potential that additional construction activity associated with future projects in the vicinity of the proposed project could occur concurrently and cumulatively impact the same sensitive receptors. Construction schedules for potential future projects are currently unknown; therefore, potential impacts to sensitive receptors that might be located within an area of overlap between emissions from two simultaneous projects are speculative. The CEQA Guidelines state that if a particular impact is too speculative for evaluation, the agency should note its conclusion and terminate discussion of the impact (Title 14, California Code of Regulations, Section 15145). This analysis is nonetheless provided in an effort to provide good faith analysis and comply with CEQA's information disclosure requirements. Air pollutant emissions associated with construction activity of future projects would be reduced through the implementation of mitigation measures required by the South Coast Air Quality Management District (SCAQMD). Cumulative PM_{10} and $PM_{2.5}$ emissions would be reduced as all future projects would be subject to SCAQMD Rule 403 (Fugitive Dust), which sets forth general and specific requirements for all construction sites in the SCAQMD. As indicated in Section 5.10, the application of architectural coatings (exterior/interior paint and other finishings) would produce VOC emissions that would exceed the SCAQMD's established quantitative significance threshold. As VOC is a precursor to ozone, construction of the proposed project along with other nearby projects would contribute to the South Coast Air Basin’s (SCAB) ozone nonattainment designation. The maximum 24-hour PM_{10} and $PM_{2.5}$ concentrations are anticipated to exceed the LST at the maximally impacted sensitive receptor in the vicinity of the project site during project construction. Fugitive dust, as well as vehicle and equipment exhaust, generated during project construction would also contribute to the SCAB nonattainment designation for PM_{10} and $PM_{2.5}$.

Operations of the project would produce VOC, NO_x, CO, SO_x, PM_{10} and $PM_{2.5}$ emissions from all combined proposed residential and nonresidential project land uses. The projected operational emissions from both area source and vehicular emissions are substantially above the SCAQMD

significance criteria for all pollutants except SO_x. Long-term operational air quality impacts are considered significant and unmitigable, even with application of all feasible mitigation measures. The cumulative effect of the proposed project and other projects in the vicinity would incrementally contribute to the SCAB's levels of O_3, NO_2, CO, PM_{10}, and $PM_{2.5}$. The location of the project within a nonattainment area for ozone PM_{10}, and $PM_{2.5}$, when combined with other foreseeable projects within the area would result in significant, unmitigable cumulative air quality impacts from both a short and long term perspective even with incorporation of all feasible area source and vehicular source mitigation measures. Because feasible mitigation measures consist of many emission reduction strategies (i.e., architectural design features, encouragement of alternative transportation, etc.), most of which help reduce emissions, current technology doesn't allow for a complete reduction of emissions given the types of development proposed. Therefore despite the City's efforts to require all feasible mitigation, significant unmitigable impacts would remain.

Global Climate Change

The project would also contribute to the overall production of greenhouse gas (GHG) emissions during construction and operation. As stated in *Section 5.10.4*, the proposed project's contribution to state, national, and GHG emission inventories and the resultant effect on global climate should be evaluated on a cumulative basis. The proposed project would generate GHG emissions, which would contribute to potential cumulative impacts of GHG emissions on global climate.

Under Section 15065 of the CEQA Guidelines, an EIR must discuss cumulative impacts if a project would have a cumulatively considerable effect on a resource, where "cumulatively considerable" is defined as "…the incremental effects of an individual project are significant when viewed in connection with the effects of past projects, the effects of other current projects, and the effects of probable future projects." However, as Section 15064(h)(4) states, "The mere existence of significant cumulative impacts caused by other projects alone shall not constitute substantial evidence that the proposed project's incremental effects are cumulatively considerable." Therefore, the fact that the proposed project would result in emissions of GHGs (chiefly carbon dioxide), and that global GHG emissions contribute to the greenhouse effect and the resultant impacts on global climate, does not mean that the proposed project would have a cumulatively considerable contribution to impacts on global climate. The potential contribution of the project to this cumulative impact is evaluated relative to whether the project could impede or conflict with the emissions reduction targets and strategies prescribed in or developed to implement AB 32.

The proposed project is evaluated with respect to the California Air Resources Board's (CARB) Climate Change Scoping Plan, which established the state's framework for meeting the goals of

AB 32. Many of the Scoping Plan measures to be adopted in the next several years will reduce GHG emissions from all development projects and their users in California. For example, adoption of the Low Carbon Fuel Standard and more stringent energy conservation standards would apply to all motor vehicle users and owners of homes and commercial properties, including those of the proposed project. Given that the GHG reduction goal of AB 32 (i.e., reduction of emissions to 1990 levels by 2020) would require a statewide reduction of approximately 30% from "business as usual" (i.e., the emissions that would occur in the absence of any regulation of GHG emissions), a large portion of a specific project's GHG emissions will result from statewide measures. Nonetheless, each development project should incorporate measures intend to achieve the goals of AB 32.

The Specific Plan incorporates several design features that reduce indirect emissions of GHGs by reducing vehicle trips and conserving water that would otherwise be consumed by the proposed project:

- Incorporates commercial (retail) and mixed-use (office/retail) components to improve jobs/housing balance and reduce vehicle trips.
- Incorporates public and private on-site recreational facilities
- Provides drought-tolerant and water-efficient landscaping for the community to reduce waste usage.
- Incorporates recycled water from Eastern Municipal Water District to supply the lake and irrigate landscaping to minimize the use of potable water.

By incorporating the commercial and mixed-use components of the proposed project, the project's residents will be able to use retail services and take advantage of job opportunities within proximity to the residential development. Thus, motor vehicle trips and their associated GHG emissions would be reduced relative to a project that would not include these nonresidential uses. The traffic impact analysis estimated that 5,020 trips are captured internally by the project for trips between the residential and commercial/mixed-use components. If these trips were required to go to off-site commercial and mixed-use locations, they would generate a minimum of 6,693 metric tons of carbon dioxide equivalent (CO_2E) of GHGs. This amount would be even larger if the project residents were required to drive farther to such uses, which would be likely given the lack of retail and commercial development in proximity to the proposed project. Additionally, there are on-site recreational facilities which would further reduce the need for longer vehicle trips associated with such uses at another location.

The use of recycled water to supply the lake and for landscape irrigation will reduce the GHG emissions associated with electricity needed for conveyance, treatment, and distribution of potable water. The estimated amount of water needed to supply the lake and irrigation of

common landscaping area (e.g., parks and greenbelts) is 402 acre-feet per year. Using recycled water would offset an equivalent amount of potable water, which would result in the generation of 1,137 metric tons CO_2E of GHG emissions from electricity for conveyance, treatment, and distribution.

Together, the incorporation of commercial/mixed-use components and use of recycled water would reduce the proposed project's GHG emissions by an estimated 7,830 metric tons CO_2E per year, or 14%, relative to the business-as-usual scenario.

In addition, the Specific Plan would reduce GHG emissions associated with vehicle trips by encouraging pedestrian and bicycle activity within the community. The project would include a 9.6-acre network of paseos and pathways linking the Beach Club and lake to all of the residential neighborhoods, commercial and mixed use areas, and the recreational amenities including the neighborhood parks and the Community Park. Neighborhood design will maximize pedestrian access to the paseo system by providing that a minimum of 50% of the streets terminate in cul-de-sacs that access the paseos.

The following design guidelines have been incorporated into the Energy Efficiency Guidelines in the Villages of San Jacinto Specific Plan to help reduce vehicle trips, electrical and natural gas usage, and conserve water, all of which would reduce the proposed project's GHG emissions.

Energy Efficiency

1. All buildings shall employ passive heating and cooling design strategies to the extent practical.
2. Shading of windows and entrance locations with a combination of structural elements and landscape materials will reduce heat gain and lower the temperature around each house.
3. Consider installing natural lighting systems such as skylights and interior transom windows to reduce energy consumption in commercial, office and municipal structures.
4. When appropriate to the architectural style, consider constructing light colored roof, which absorb less heat, reduce solar heat gain, and reduce use of mechanical cooling systems.
5. Use energy-efficient appliances and programmable thermostats to reduce the amount of consumed energy and reduce utility bills.
6. Automatic devices to turn off lights after business hours shall be used to the extent feasible in the commercial and business park land uses. Similarly, install timers on outdoor lighting to limit operating hours.

7. Install fluorescent bulbs in all indoor and outdoor fixtures unless unsuitable for the application.
8. Offer homebuyers the option of a natural gas stove, which reduces the consumption of electricity.
9. Use of passive solar energy minimizes the consumption of electricity. If possible, offer additional energy conservation features as homebuyer options, including but not limited to:
    a. Photovoltaic panels for electrical power needs of home.
    b. Photovoltaic landscape lighting, gate openers, water features.
    c. Solar water heating system.

Water Conservation

1. Drought tolerant and native plants are required as part of the plant palette, as required by Riverside County Ordinance No. 859.
2. Use a drip irrigation system and/or zoned irrigation system with a rain sensor shutoff feature.
3. Consider xeriscape landscape treatments instead of lawns. Where lawns or gardens are proposed, incorporate detention grading and/or construct as a swale to allow for maximum detention and control of stormwater flows.
4. Utilize water efficient faucets, high-efficiency toilets (HETs), and water-conserving shower heads in residential homes.

Landfill Waste

1. During building construction, use long-lasting products, such as engineered lumber and durable, non-combustible flooring, siding, and roofing materials, if feasible.
2. Consider the use of sustainable building materials for use during building design and construction.

Pedestrian Activity and Bicycle Paths

1. Provide on-site improvements, such as sidewalks or pedestrian walkways, to promote on-site pedestrian activity and reduce the amount of vehicle trips within the community.
2. Provide a pedestrian access network and pedestrian facilities to internally link all uses and connect to all existing/planned external streets and public facilities.

3. Provide a designated bicycle route connecting all units, on-site bicycle parking facilities, and all streets contiguous with the community.
4. Design traffic calming elements to encourage walking and biking.

Implementation of these design guidelines would likely result in additional reductions in the GHG emissions from natural gas and electrical usage. However, those emission reductions cannot be quantified because the guidelines do not provide sufficient detail to compute the actual reductions in natural gas and electrical usage.

The Climate Change Scoping Plan recommends strategies for implementation at the statewide level to meet the goals of AB 32. The Scoping Plan recommendations serve as statewide strategies to reduce the state's existing GHG emissions and proposed project's contributions. Although a framework for the adoption of specific regulations and measures, the Scoping Plan is the current state's plan to reduce GHG emissions. *Table 6.0-2, Project Consistency with Scoping Plan GHG Emission Reduction Strategies*, highlights measures to be developed under the Scoping Plan that would be applicable to the proposed project or its users. The proposed project's consistency with the applicable Scoping Plan measures is assessed.

Table 6.0-2
Project Consistency with Scoping Plan GHG Emission Reduction Strategies

Scoping Plan Measure	Measure Number	Project Consistency
Pavley Motor Vehicle Standards (AB 1493)	T-1	The proposed project's residents and employees would purchase vehicles in compliance with CARB vehicle standards that are in effect at the time of vehicle purchase.
Limit High GWP Use in Consumer Products	H-4	The proposed project's residents would use consumer products that would comply with the regulations that are in effect at the time of manufacture.
Motor Vehicle Air Conditioning Systems – Reduction from Non-Professional Servicing	H-1	The proposed project's residents would be prohibited from performing air conditioning repairs and required to use professional servicing.
Tire Pressure Program	T-4	Motor vehicles driven by project residents and employees would maintain proper tire pressure when their vehicles are serviced.
Low Carbon Fuel Standard	T-2	Motor vehicles driven by project residents and employees would use compliant fuels in the future.
Water Use Efficiency	W-1	The Specific Plan includes measures to minimize water use and maximize efficiency.
Water Recycling	W-2	The proposed project will use recycled water for the lake and irrigation of common landscaped areas.
Solar Water Heating (AB 1470)	CR-2	The Specific Plan includes an energy efficiency guideline to offer home purchasers the option of installing solar hot water heaters.
Million Solar Roofs	E-4	The Specific Plan includes an energy efficiency to offer home purchasers the option of installing photovoltaic panels for electrical power needs.

Table 6.0-2 (Continued)

Scoping Plan Measure	Measure Number	Project Consistency
Green Buildings	GB-1	The proposed project will be required to be constructed in compliance with state or local green building standards in effect at the time of building construction.
Air Conditioning Refrigerant Leak Test During Vehicle Smog Check	H-5	Motor vehicles driven by the proposed project's residents and employees would comply with the leak test requirements during smog checks.
Renewable Portfolios Standard (33% by 2020)	E-3	The electricity used by residents and businesses in the proposed project will benefit from reduced GHG emissions resulting from increased use of renewable energy sources.
Energy Efficiency Measures (Electricity)	E-1	The proposed project will comply with energy efficiency standards for electrical appliances and other devices at the time of building construction.
Energy Efficiency (Natural Gas)	CR-1	The proposed project will comply with energy efficiency standards for natural gas appliances and other devices at the time of building construction.
Greening Public Schools	GB-1	The proposed school would meet green building standards that are in effect at the time of design and construction.
Greening New Residential and Commercial Construction	GB-1	The proposed project's residential and commercial buildings would meet green building standards that are in effect at the time of design and construction.
Greening Existing Homes and Commercial Buildings	GB-1	The proposed project's residential and commercial buildings would meet retrofit standards when they become effective.

SOURCE: CARB 2009.

In addition to the strategies being developed under the Climate Change Scoping Plan, the Attorney General and others have recommended mitigation measures that can be applied to a project to reduce its GHG contribution. The Attorney General's list (Office of the California Attorney General 2008) includes many of the measures that are project design features or are incorporated into the Specific Plan's Energy Efficiency Guidelines. These include, but are not limited to, the following:

- Design buildings to be energy efficient. Site buildings to take advantage of shade, prevailing winds, landscaping and sun screens to reduce energy use.
- Install efficient lighting and lighting control systems. Use daylight as an integral part of lighting systems in buildings.
- Install light colored “cool” roofs, cool pavements, and strategically placed shade trees
- Install energy efficient heating and cooling systems, appliances and equipment, and control systems.
- Limit the hours of operation of outdoor lighting.

- Install solar and wind power systems, solar and tankless hot water heaters, and energy-efficient heating ventilation and air conditioning.
- Create water-efficient landscapes.
- Install water-efficient irrigation systems and devices, such as soil moisture-based irrigation controls.
- Use reclaimed water for landscape irrigation in new developments and on public property. Install the infrastructure to deliver and use reclaimed water.
- Design buildings to be water-efficient. Install water-efficient fixtures and appliances.
- Include mixed-use, infill, and higher density in development projects to support the reduction of vehicle trips, promote alternatives to individual vehicle travel, and promote efficient delivery of services and goods.
- Preserve and create open space and parks.
- Create travel routes that ensure that destinations may be reached conveniently by public transportation, bicycling or walking.
- Incorporate bicycle lanes and routes into street systems, new subdivisions, and large developments
- Create bicycle lanes and walking paths directed to the location of schools, parks and other destination points.

In January 2008, the California Air Pollution Control Officers Association (CAPCOA) published *CEQA and Climate Change: Evaluating and Addressing Greenhouse Gas Emissions from Projects Subject to the California Environmental Quality Act* (CAPCOA 2008). This white paper is "intended as a resource, not a guidance document. It is not intended, and should not be interpreted, to dictate the manner in which an air district or lead agency chooses to address greenhouse gas emissions in the context of its review of projects under CEQA" (CAPCOA 2008). However, this document provides an extensive list of potential GHG mitigation measures; however, many of them would be only implementable by the users of the proposed project and not enforceable by the City or the applicant. Again, many of them, as listed below, are project design features or incorporated into the Energy Efficiency Guidelines:

- Bike parking
- Proximity to bike path/bike lanes
- Pedestrian network
- Orientation to existing/planned transit, bikeway, or pedestrian corridor
- Suburban mixed use

- No wood-burning fireplaces or stoves
- Energy efficient appliances
- Shading mechanisms
- Programmable thermostats
- Passive heating and cooling systems.

Based on the analysis in *Table 6.0-2*, the proposed project would substantially reduce its contribution to GHG emissions and global climate due to its consistency with the strategies and measures in the Scoping Plan, as well as mitigation measures suggested by the Attorney General and CAPCOA. In addition, the proposed project would result in GHG emissions of approximately 49,650 metric tons per year (0.05 million metric tons) as shown in *Table 5.10-13*, which is 14% below the level that would have been emitted under a business-as-usual scenario. Furthermore, compared to the estimated GHG for all sources in California (423 million metric tons, excluding out-of-state electrical generation, in 2004), the project would result in a contribution of approximately 0.012% to California's GHG emissions inventory without accounting for the implementation of statewide emissions that would reduce both the project's and the state's emission inventories. In light of the project's consistency with the Scoping Plan and other suggested measures through its design features and Energy Efficiency Guidelines and its substantial reduction from business as usual, it is concluded that the proposed project would not impede or conflict with the emissions reduction targets and strategies prescribed in or developed to implement AB 32. Therefore, the proposed project would not result in a cumulatively considerable contribution to global climate change, and this cumulative impact would be less than significant.

Noise

Cumulative noise impacts are discussed in terms of traffic related noise and a general increase in urbanization in an area. A project specific contribution to cumulative traffic noise would be evaluated on an individual basis, and if significant impacts are identified (e.g., non-compliance with noise standards) then mitigation requirements would be imposed. In the long term, the increase in traffic noise from the proposed project and cumulative developments (i.e., General Plan build-out) is calculated to range from 5 to 7 dB, which is a noticeable change in the noise environment. The noise increase associated with traffic from cumulative developments is therefore considered potentially significant. However, the project's contribution to cumulatively significant traffic noise impacts is less than significant (1 dB or less increase, which by itself is not a discernible increase). Consequently, mitigation is not required for the project's contribution to off-site noise impacts associated with General Plan build-out traffic volumes but is required

for the cumulatively significant impact, Mitigation to address this significant cumulative noise impact is included in Section 5.11.5, Mitigation Measures, Mitigation Measure 5.11-a.

Public Services and Utilities

The project would involve an incremental increase in demand for public facilities. As described in *Section 5.12, Public Services and Utilities*, consistency and contribution to City public facility fee structures would eliminate adverse cumulative impacts on local sewer, water, police and fire services. The proposed project includes development standards that would apply to all future build-out of the planning area which specifically includes development elements and/or policies and measures to ensure that adequate public facilities and services are provided in conjunction with build-out of the development.

Hazards/Risk of Upset

Potential hazards associated with development of the project and development of surrounding projects would be site-specific and can be mitigated on a project-by-project basis. Each project is required to ensure that no hazardous conditions exist at the project site or that the project itself would not result in a hazard to the public or the environment. The proposed project could potentially result in significant hazard impacts, however mitigation has been provided which would reduce project-specific impacts to a level below significance. Because all projects are required to fully mitigate any on-site hazards, residual cumulative impacts related to hazards/risk of upset would not occur.

INTENTIONALLY LEFT BLANK

SECTION 7.0
EFFECTS FOUND NOT TO BE SIGNIFICANT

7.1 INTRODUCTION/PURPOSE

Section 15128 of the CEQA Guidelines requires that an EIR briefly describe any potential environmental effects that were determined not to be significant during the initial project scoping and, therefore, were not discussed in detail in the EIR.

Several subjects required to be analyzed under CEQA were determined not to be potentially significant during Initial Study preparation and during the public scoping period. Therefore, these environmental issues have not been analyzed in the EIR and have received no further consideration.

7.2 ISSUES FOUND NOT TO BE SIGNIFICANT

Mineral Resources

The main mineral resource recovery areas within western Riverside County are in the Temescal Wash area, the Santa Ana River Valley, and sporadic pockets dotted throughout the lowland areas. Valuable sand, gravel, and crushed rock resources, which are extremely important to the local and regional construction industry, are located within these areas. The project is located within a "MRZ-3" designation in the Riverside County General Plan Open Space Element. "MRZ-3" indicates that there are significant mineral deposits within the area; however, the significance of the deposits have yet to be determined (County of Riverside 2003, p. OS-26 and Figure OS-5).

The project site is underlain by alluvial materials composed of inter-bedded sands and silts (Leighton and Associates 2004). Mineral resources are generally composed of gravels and rock materials. The site, therefore, does not support mineral resources that are considered to be of high value.

Population and Housing

The CEQA Appendix G Checklist includes two basic questions related to population and housing: (1) Will the project induce substantial population growth in an area, either directly or indirectly, and (2) Will the project displace substantial numbers of people or residences, necessitating the construction of replacement housing elsewhere? The first question relates to the project's growth inducing nature; therefore, this issue is discussed in *Section 8.0, Growth Inducing Impacts*. The second question relates to displacement, which is an "Effect Found Not to be Significant" and is therefore discussed below.

One unoccupied residence is currently located on the project site. The project would therefore involve the removal of this dwelling. The loss of one residence would be sufficiently offset by the construction of up to 1,329 new residential units on the site. Therefore, significant impacts related to population and housing displacement would not occur.

Noise

The CEQA Appendix G Checklist includes two questions related to noise, which were not discussed in *Section 5.11, Noise*: (1) For a project located within an airport land use plan or, where such a plan has not been adopted, within 2 miles of a public airport or public use airport, would the project expose people residing or working in the project area to excessive noise, and (2) For a project within the vicinity if a private airstrip, would the project expose people residing or working in the project area to excessive noise levels? The project is not located within 2 miles of a public airport or private use airport. Therefore, impacts associated with aircraft noise to people residing on the project site would not occur.

SECTION 8.0
GROWTH INDUCING IMPACTS

Section 15126.2(d) of the CEQA Guidelines mandate that the growth inducing nature of the proposed project be discussed. This CEQA Guideline states the growth inducing analysis is intended to address the potential for the project to "foster economic or population growth, or the construction of additional housing, either directly or indirectly, in the surrounding environment." Further, as discussed in *Section 7.0, Effects Found Not Significant*, the CEQA Appendix G Checklist (Population and Housing) also mandates that a CEQA document speak to the project's likelihood to induce substantial population growth in an area, either directly (for example, by proposing new homes or businesses) or indirectly (for example, through extension of roads or other infrastructure).

A project may be distinguished as either facilitating planned growth or inducing unplanned growth. Facilitating growth is relating to the establishment of direct employment, population or housing growth that would occur within a project site. Inducing growth is related to lowering or removing barriers to growth or by creating an amenity or facility that attracts new population/economic activity. For purposes of this EIR analysis, a significant growth inducement impact would occur if the project, and all associated infrastructure improvements, directly or indirectly remove obstacles to growth such that the induced growth would significantly burden existing community services, the environment or cause a demand for General Plan Amendments.

The large-scale nature of the project would contribute substantial funding for roadway and utility infrastructure improvements needed to accommodate growth planned in the western portion of the City of San Jacinto. The project would not contribute excess infrastructure capacity that would induce growth in surrounding areas, but would rather help accommodate the continued population influx in western Riverside County over the next several decades. Improvements to transportation, utilities and public service infrastructure as part of the project would help alleviate existing infrastructure deficiencies and accommodate planned growth, but would not result in a significant amount of unplanned growth to the area. For example, water and sewer pipelines in North Sanderson Avenue are already sized appropriately to service the site, the project would not result in an extension of large-capacity pipeline network beyond what is already in place that could then facilitate easy connections by other planned developments within the area. Similarly, while the project would result in a General Plan Amendment, significant growth inducing impacts to land use would not occur as this project site and the surrounding land is planned for urban uses. No features of the proposed project, on its own, would encourage or enhance the likelihood of growth in the surrounding areas other than anticipated under the applicable general plan. Therefore, while the project will induce planned population growth in the area, it will not induce growth in the area that is not already planned and permitted under the City's General Plan. Therefore growth inducing impacts would not occur.

INTENTIONALLY LEFT BLANK

SECTION 9.0
SIGNIFICANT IRREVERSIBLE ENVIRONMENTAL CHANGES

9.1 Significant Effects Which Cannot be Avoided

Section 15126.2(b) of the CEQA Guidelines requires an EIR to identify significant environmental effects that cannot be avoided if the proposed project is implemented. As discussed in this EIR, implementation of the proposed project would result in significant project impacts to agriculture and air quality and contribute to a significant unavoidable impact for cumulative traffic conditions. As discussed in Section 5.3, Agricultural Resources, there is no feasible mitigation to replace agricultural resources and this impact will therefore remain significant and unavoidable. Even with application of feasible mitigation measures, significant unavoidable air quality impacts will occur due to application of architectural coatings, potential CO "hotspots," and projected operational emissions from both area source and vehicular emissions. Because the City can not guarantee that the MCP and SR 79 projects would be in place prior to project build-out, the project would contribute to a significant, unavoidable cumulative impact to regional traffic service levels in the absence of these facilities.

9.2 Significant Irreversible Environmental Changes Which Would be Caused by the Project Should it be Implemented

CEQA Section 15126.2(c) requires the evaluation of the uses of nonrenewable resources during the initial and continued phases of a project when a large commitment of such resources makes removal or non-removal or non-use thereafter unlikely. Approval of the proposed development of the site from an agricultural operation to a residential/commercial/business park community commits the area to urban uses. The project would permanently remove approximately 475.1 acres of land from local agricultural production. However, the change in use is both planned and projected. The proposed project would require commitment of nonrenewable resources associated with construction and long-term operation, including but not limited to, lumber and other related forest products, sand, gravel and concrete, asphalt, petrochemical construction materials, steel, copper, lead and other metals, water, fuels and energy. Use of these resources would represent an incremental effect on the regional consumption of these commodities. Implementation of the Villages of San Jacinto project would involve consumption of energy resources, such as electricity and natural gas, derived from non-renewable sources such as fossil fuels.

The predominant irreversible environmental change that would occur as a result of the project would be continuation of planned commitment of land resources to urban/developed uses. This would constitute a permanent change. Once construction occurs, reversal of the land to its

original condition is nearly impossible. Other permanent changes would include more traffic and hence noise, permanent landform alteration, increased human presence in the area and the transition from a rural to urban development. Irreversible commitments of energy resources would occur with the proposed project. These resources would include electricity, natural gas, potable water and building materials.

The CEQA Guidelines require that an EIR identify "feasible measures which could minimize significant adverse impacts, including where relevant, inefficient and unnecessary consumption of energy" (Title 14, California Code of Regulations, Section 15126.4(a)(1)). Examples of energy conservation measures are provided in Appendix F of the State CEQA Guidelines (Section 15126.4(a)(1)(C)). The proposed project will consume energy in several different forms: gasoline and diesel fuels for motor vehicles; natural gas for water and space heating and cooking; electricity to operate lighting, heating and air conditioning systems, water transport including water for landscaping, and other uses.

Appendix F, Energy Conservation, of the CEQA Guidelines, recommends that EIRs include a discussion of the potentially significant energy impacts of proposed projects, with particular emphasis on avoiding or reducing inefficient, wasteful and unnecessary consumption of energy (see also Public Resources Code Section 21100(b)(3)). Appendix F also states that mitigation measures may include siting, orientation, and design to minimize energy consumption, including transportation energy, water conservation and solid-waste reduction; the potential for reducing peak energy demand; alternate fuels (particularly renewable ones) or energy systems; energy conservation which could result from recycling efforts; and other potential measures to reduce wasteful, inefficient and unnecessary consumption of energy during construction, operation, maintenance and/or removal.

The Specific Plan identifies elements in the site planning, design and construction phases that would be implemented to achieve a high level of energy efficient performance. Following standard planning and building practices typically ensures compliance with building code requirements and issuances of the necessary permits; however, implementation of the Specific Plan’s Energy Efficient Guidelines are intended to reduce energy use even further, thereby reduce operating costs and contributing to the reduction in environmental impacts associated with air quality, hydrology, water quality, hazards, and utilities. The Specific Plan’s Energy Efficient Guidelines, summarized below, are consistent with Appendix F recommended mitigation measures.

The Energy Efficiency Guidelines include the following strategies to minimize the energy demands of the proposed project:

- Passive heating and cooling design strategies such as orientation
- Natural ventilation, including cross-ventilation in residential units

- High insulation values, energy efficient windows including high performance glass
- Light-colored roofing and exterior walls
- Window shading through strategically placed landscaping
- Landscaping that provides shading during appropriate seasons
- Natural lighting systems such as skylights and interior transom windows in commercial, office and municipal structures
- Energy-efficient appliances and programmable thermostats.

The Specific Plan also includes water conservation strategies that would reduce water demand and the associated electrical consumption for water transport and distribution. The water conservation strategies include:

- Utilization of water-efficient faucets, high-efficiency toilets (HETs), and water-conserving shower heads in residential homes
- Drought tolerant and native plants, as required as part of the plant palette in the Specific Plan
- Installation of xeriscape landscape treatments instead of lawns
- Drip irrigation systems and/or zoned irrigation systems with a rain sensor shutoff feature
- Use of reclaimed waste water for irrigation of community landscaping.

In addition to water conservation, smart landscaping practices included in the Specific Plan would also reduce the reliance on mechanical cooling systems and the associated electrical consumption. Shade-producing trees planted in accordance with the Specific Plan's Shade Standards, would minimize the heat island effect, while permeable materials reduce the amount of heat absorbed and re-radiated from the surface and prevent additional solar heat gain surrounding residences. The Specific Plan also includes improvements to the existing street network to promote on-site bicycle and pedestrian activity and reduce the amount of vehicle trips and associated motor vehicle fuel use within the community. These improvements include:

- Development of sidewalks or pedestrian walkways
- Pedestrian access network and pedestrian facilities to internally link all uses and connect to all existing/planned external streets and public facilities
- Designated bicycle route connecting all units, on-site bicycle parking facilities, and all streets contiguous with the community
- Traffic calming elements to encourage walking and biking.

In addition to the Specific Plan's Energy Efficient Guidelines, the commercial/mixed-use elements of the proposed project would reduce total vehicle-miles traveled and associated motor vehicle fuel use. As commercial and retail uses would be within close distance to residential uses, trip lengths would be reduced. Development of commercial uses within walking or bicycling distance of residences would help to reduce reliance on motor vehicles. Although the implementation of the proposed project would involve consumption of energy resources, such as electricity and natural gas, derived from non-renewable sources such as fossil fuels, the project incorporates energy conservation strategies that would reduce the project's incremental effect on regional energy consumption.

SECTION 10.0
PROJECT ALTERNATIVES

CEQA requires that an EIR evaluate a "reasonable" range of alternatives. According to the CEQA Guidelines, "…an EIR shall describe a range of reasonable alternatives to the project, or to the location of the project, which would feasibly attain most of the basic objectives of the project but would avoid or substantially lessen any of the significant effects of the project, and evaluate the comparative merits of the alternatives (Cal. Code Regs., Title 14, Section 15126.6(a)). Specifically, the Guidelines require the analysis of the No Project Alternative and alternatives which would be "capable of avoiding or substantially lessening any significant effects of the project" (Cal. Code Regs., Title 14, Section 15126.6(b)). It also requires a discussion of why other alternatives were rejected if they were considered in developing the proposed project and still would meet the project objectives. Although an exhaustive analysis is not necessary, an EIR "must consider a reasonable range of potentially feasible alternatives that will foster informed decision making and public participation" (Cal. Code Regs., Title 14, Section 15126.6(a)).

Pursuant to the guidelines stated above, a range of alternatives to the proposed project are considered and evaluated in this EIR. These alternatives were developed in the course of project planning, environmental review, and public hearings. The discussion in this section provides:

In order to summarize these project alternatives, as suggested in CEQA Section 15126.6(d), a matrix has been prepared to summarize and compare the impacts of each project alternative.

10.1 ALTERNATIVES CONSIDERED BUT REJECTED

The following alternative was eliminated from further consideration.

10.1.1 Alternative Site Location

Off-site alternative locations were considered as part of the alternatives process. Per CEQA Guidelines Section 15126.6(f)(2)(A), the key question and first step in analysis of the off-site location is whether any of the significant effects of the project would be avoided or substantially lessened by putting the project in another location.

It should be noted that the availability of an alternative site does not in and of itself reduce impact potential. It is expected that developing a similar project would result in a similar array of project impacts and would simply transfer this impact potential to areas surrounding the alternate site location. For these reasons, an alternate site location would not necessarily be preferred over the proposed project site.

Project Description

Due to the undeveloped nature and existing land use designations found throughout much of the areas surrounding the project vicinity, suitable sites exist for this type/scale of development in the surrounding area.

Environmental Analysis

Because of the type, number of units and densities proposed, a similar amount of land would be required to accommodate the project at a different location. Depending on the location of this alternative, it would be expected to result in similar impacts to aesthetics, biological resources, cultural resources, geology/soils hazards and hazardous materials, hydrology and water quality, land use and planning, noise and public services to that of the proposed project at its present location, and would require a similar level of mitigation to reduce identified impacts to less than significant levels. If an alternative site included important farmland as designated by the California Resources Agency, it would result in a similar direct unavoidable impact due to loss of agricultural resources. An alternative location would also have unavoidable air quality impacts due to application of architectural coatings, potential CO "hotspots," and projected operational emissions from both area source and vehicular emissions. It would also likely have significant urban/rural land use conflicts between the planned development and existing agricultural uses in the area. The trip generation associated with the project would be the same; therefore, the alternative site location would be expected to contribute to a significant unavoidable impact for cumulative traffic conditions if the MCP and SR 79 projects are not in place upon completion.

Consideration/Elimination

Per CEQA Guidelines Section 15126.6 (f)(1), "Among the factors that may be taken into account when addressing the feasibility of alternatives are site suitability, economic viability, availability of infrastructure, general plan consistency, other plans or regulatory limitations, jurisdictional boundaries (projects with a regionally significant impact should consider the regional context), and whether the proponent can reasonably acquire, control or otherwise have access to the alternative site (or the site is already owned by the proponent)." The applicant cannot reasonably acquire, control, or otherwise have access to an alternative site; therefore, an alternative site is infeasible. Additionally, since project related impacts would be similar for surrounding area properties, project development on an alternative site would simply shift impacts from one area to another, without the benefit of removing any significant unavoidable impacts.

10.2 ALTERNATIVES UNDER CONSIDERATION

Three alternatives were deemed appropriate for analysis in this EIR section. Because it was initially determined that the "Reduced Density" and "Existing General Plan Designation"

alternatives could feasibly accomplish most of the basic objectives of the project and could avoid or substantially lessen one or more of the significant effects, these two alternatives are analyzed. While the third alternative, "No Project/No Development" would not likely meet most of the project objectives, CEQA requires that this scenario also be analyzed. Inclusion of the No Project/No Development alternative provides the public/decision makers with a reasonable range of choices and allows comparison of impacts of approving the proposed project with the impacts of not approving the proposed project.

Each alternative is analyzed for potential environmental effects including Landform Alteration/Aesthetics, Agricultural Resources, Biological Resources, Geology and Soils, Cultural Resources, Paleontological Resources, Hydrology and Water Quality, Transportation, Circulation and Access, Air Quality, Noise, Public Utilities and Services and Hazards/Risk of Upset. Due to the lack of significant Land Use/Planning impacts, this issue is not discussed in this alternatives analysis. After each environmental issue is analyzed, a consideration/elimination discussion follows. This discussion relates to the project's feasibility as well as the project's relationship to the project objectives included in *Section 3.0, Project Description*.

CEQA Section 15126.6(c) indicates that a project alternative should meet "most" of the basic objectives of the project. In an attempt to provide an equal analysis factor, "most" is met if over eight of the twelve project objectives are met (roughly two thirds). To determine feasibility, site suitability, economic viability, availability of infrastructure, general plan consistency and other regulatory/planning limitations were considered.

10.2.1 No Project/No Development Alternative

Project Description

The No Project/No Development Alternative assumes that the project site would not be developed and the existing land uses (agricultural operations) present would remain.

Environmental Analysis

Landform Alteration and Aesthetics

The No Project/No Development Alternative would maintain existing aesthetic conditions on the site and would continue to contribute to the existing agricultural nature of the western San Jacinto Valley area. However, none of the proposed landscape improvements along adjacent roadways would occur without project development.

Agricultural Resources

The No Project/No Development Alternative would result in the continuance of agricultural resource use on the project site. Significant, unmitigable impacts to agricultural resources (such as would occur with the proposed project) would be avoided. The persistence of agricultural use on the site would maintain the non-conforming use on the site as the site is planned for residential and commercial land uses in the existing General Plan Planned Land Use Map. Due to the existing residential General Plan designation, it is reasonable to assume that future development proposals will be brought forward for this project site. Therefore, the No Project/No Development alternative may not ensure that agricultural resources remain on site well into the future.

Biological Resources

The No Project/No Development Alternative would not result in any direct impacts to on-site biological resources. All impacts to biological resources present on site would be avoided.

Geology and Soils

Potential geologic impacts related to seismically induced earth movement would be avoided under the No Project/No Development Alternative. The existing faults located on site would continue to exist and not pose a risk to structures due to the undeveloped nature of the site.

Cultural Resources

This alternative would not involve disturbing any subsurface material that could potentially support cultural resources beyond existing agricultural activities. It is not possible to predict the type of agricultural use that would remain on the project site; if future agricultural uses were to occur on site which required excavation or heavy land disturbance, if present, cultural resources may be impacted.

Paleontological Resources

This alternative would not involve disturbing any subsurface geologic formations that could potentially support paleontological resources as would the proposed project. It is not possible to predict the type of agricultural use that would remain on the project site; if future agricultural uses were to occur on site which required excavation or heavy land disturbance, if present, paleontological resources may be impacted.

Water Resources and Water Quality

Potential impacts associated with increased urban runoff, such as the introduction of petroleum products from paved surfaces would be avoided under the No Project/No Development Alternative. However, structural systems are not currently in place to control the pollutants associated with the existing land uses. Based on the proximity of the site to the San Jacinto River, potential hazards to runoff and water quality from the existing agricultural uses may be present. Further, no development on the site would eliminate the potential for contribution to the City's overall master drainage plan/infrastructure construction within the western San Jacinto area.

Transportation, Circulation and Access

This alternative would not promote additional trips along North Sanderson, Cawston Avenue, Odell Avenue and other nearby roadways such as SR 79, State Street, Ramona Expressway, SR 74 and Ramona Boulevard. It should be noted that the no project alternative would not assist the City of San Jacinto in completing circulation infrastructure in this growing area of the City due to the elimination of proposed improvements being made by the applicant and by no contribution of TUMF fees from project development.

Air Quality

The No Project/No Development Alternative would avoid the air quality impacts associated with site grading, construction, vehicular emissions and building operations.

Noise

Noise impacts associated with the proposed project would be avoided by the No Project/No Redevelopment Alternative. However, as the western portion of the City of San Jacinto continues to be built-out and development/traffic increases along North Sanderson Avenue, Cawston Avenue, Odell Avenue and other surrounding streets, the ambient noise setting within the area will increase regardless of project implementation. The project's elimination would not necessarily improve the existing and future noise environment.

Public Services and Utilities

The elimination of development on this site would reduce the demand for local public services and facility capacity and would also not provide for expansion of infrastructure.

Hazards/Risk of Upset

The potential for additional hazards and the risk of upset of unknown hazards would not occur under this alternative. While implementation of the No Project/No Development alternative would not disturb soils on site that may result in a release of contaminants, it would also not result in the beneficial effect of cleanup on the site.

Relationship to Project Objectives

The No Project/No Development Alternative WOULD meet the following project objectives:

- Consider topographic, geologic, hydrologic, and environmental opportunities and constraints to create a design which safely accommodates seismic and hydrologic hazards.

This alternative would NOT meet the following project objectives (explanations follow each objective and have been *italicized*):

- Provide for the establishment of a master-planned community through implementation of a Specific Plan, consisting of a maximum of 1,329 dwelling units, which is consistent with the scale and character of planned land uses in surrounding areas.

This alternative would result in continuing agricultural use and vacant fallow land that would not result in establishment of a master-planned community.

- Provide a variety of detached single-family lot sizes in traditional and non-traditional subdivision layouts that offer a wide range of affordability to meet the changing economic and demographic profile of the City of San Jacinto.

This alternative would not result in any new housing opportunities.

- Provide public and private recreational amenities for the benefit of residents of this community and of the City of San Jacinto.

There would be no new recreational amenities associated with this alternative.

- Provide drought-tolerant and water-efficient landscaping for the community.

No new landscaping of any kind would be provided under this alternative.

- Incorporate recycled water from EMWD to supply the lake and irrigate landscaping to minimize the use of potable water.

The agricultural uses on site would presumably continue to use primarily recycled water.

- Provide development opportunities for municipal, office, professional, and neighborhood retail commercial land uses within the community to support the economic growth of the City and to reduce the reliance of automobile use within the surrounding community.

The no project alternative would not provide any these development opportunities and would not reduce the length of automobile trips in the surrounding community.

- Provide a system of public and community facilities within residential neighborhoods to support development in an efficient and timely manner.

None of the public and community amenities would be provided under this alternative.

- Provide a development with unified design elements, such as architecture, landscaping, color palette, paving, walls, fencing, signage, and entry treatments.

This alternative would not allow an opportunity to provide any such design elements as the project would not be implemented.

- Develop an environment that is visually attractive, efficient, and effectively organized, which includes a pleasing landscape palette.

No new landscaping of any kind or any developed environment would be provided under this alternative.

- Integrate the project with the character of the surrounding community and establish development that results in logical, coordinated growth.

- Establish a circulation system that meets projected traffic volumes and accommodates a variety of transportation modes and encourages alternatives to automobile use within the community.

The no project alternative does not provide circulation improvements or encourage alternative transportation modes.

10.2.2 Existing General Plan Designation Alternative

Project Description

As shown on Figure 5.1-3, General Plan Comparison vs. Proposed Specific Plan, existing General Plan designations establish 136.5 acres of low density residential and 239.5 acres of medium density residential. This would allow for a maximum of 2,390 medium density dwellings (10 du/ac maximum) and up to 682 low density dwellings (5 du/ac maximum) for a total of 3,072 dwelling units under the existing General Plan. This compares with the proposed project which would result in 657 medium density dwellings and 359 low density dwellings for a total of 1,016 dwellings. Therefore, this alternative could result in more than three times the number of dwellings proposed under the project. This alternative would also provide 54.4 acres of commercial uses along Sanderson Avenue as opposed to a combined 49 acres of commercial and mixed uses under the project. This alternative results in fewer acres of open space/parks (44.7 as opposed to 110.5 under the project) and does not provide for a future high school on site.

Environmental Analysis

Landform Alteration and Aesthetics

This alternative would represent a similar change in urban land use as it would also appear as a developed suburban neighborhood in the western San Jacinto Valley. However, it does not provide as many transitions between land uses and would not guarantee the extensive open space amenities, street landscaping and landscaped trails that provide a visual buffer between land uses. Therefore, this alternative is viewed as slightly inferior to the project, but it is expected that significant visual impacts could be mitigated.

Agricultural Resources

This alternative would be similar to the proposed project in that it would eliminate agricultural land use from the project site.

Biological Resources

This alternative would result in similar impacts as the proposed project as it would eliminate existing biological resources on site. This project alternative does not provide for fewer impacts to biological resources compared to the proposed project.

Geology and Soils

Similar impacts related to seismic hazards would occur under this project alternative. It is anticipated that similar mitigation measures would be imposed and similar to the proposed project, result in all significant impacts being mitigated.

Cultural Resources

Because the presence of undiscovered cultural resources is unknown for both this and the proposed project alternative, risk of significant impacts would be the same as the proposed project. It is anticipated that similar mitigation measures would be imposed as for the proposed project which would result in all significant impacts being mitigated.

Paleontological Resources

Because the presence of paleontological resources is unknown for both this and the proposed project alternative, risk of significant impacts would be the same as the proposed project. It is anticipated that similar mitigation measures would be imposed and similar to the proposed project, result in all significant impacts being mitigated.

Water Resources and Water Quality

Similar water quality impacts would result under this alternative as described for the proposed project. The project site would likely be susceptible to the same flooding and groundwater hazards as outlined for the proposed project. It is anticipated that application of mitigation measures such as those required of the proposed project would have similar impact reducing effects for this alternative.

Transportation, Circulation and Access

Due to the increase in the number of dwelling units, the existing General Plan land use scenario would result in higher traffic volumes from a greater number of residents and more intensive construction phase as compared to the proposed project. Therefore, there is no guarantee that this alternative could mitigate all significant traffic impacts and is therefore viewed as inferior to the proposed project.

Air Quality

Due to three times more dwelling units allowed under this alternative, the existing General Plan land use scenario would result in higher traffic volumes and result in higher air quality impacts compared to the proposed project. Also, the application of architectural coatings would contribute higher overall VOC emissions and would be expected to exceed the daily threshold

for a greater number of days. Therefore, this alternative is viewed as environmentally inferior to the project due to anticipated greater air quality impacts.

Noise

Although similar noise levels would be expected, due to the increase in number of dwelling units, the length of the construction period is likely to be longer under this alternative. Also, the increased traffic volumes associated with the greater number of dwellings can be expected to result in higher noise levels on surrounding roadways as compared to the project. Therefore, this alternative is viewed as environmentally inferior to the project due to anticipated greater noise impacts.

Public Services and Utilities

Due to the more intensive land use anticipated with this alternative, additional new residents would likely result in increased demand on public utilities and services including police, fire, water, wastewater, solid waste disposal, etc. While it is assumed that an increase in demand for these services could be off-set by mitigation, a greater impact to public services and utilities would likely result from the proposed alternative.

Hazards/Risk of Upset

Similar hazards would result under this alternative as anticipated for the proposed project. Hazardous materials would need to be disposed of and any remaining soil hazards remediated. Further, hazards associated with former cattle raising areas would be the same type as anticipated for the proposed project.

Relationship to Project Objectives

The Existing Zoning/General Plan Designation alternative WOULD meet the following project objectives:

- Provide drought-tolerant and water-efficient landscaping for the community.
- Consider topographic, geologic, hydrologic, and environmental opportunities and constraints to create a design that safely accommodates seismic and hydrologic hazards.
- Reinforce the community identity of the project through control of project design elements such as architecture, landscaping, color palette, paving, walls, fencing, signage and entry treatments.
- Develop an environment that is visually attractive, efficient, and effectively organized, which includes a pleasing landscape palette.

- Integrate the project with the character of the surrounding community and establish development that results in logical, coordinated growth.
- Provide a system of public and community facilities within residential neighborhoods to support development in an efficient and timely manner.
- Provide a development with unified design elements, such as architecture, landscaping, color palette, paving, walls, fencing, signage, and entry treatments.

All of the above objectives would likely be required under a different Specific Plan for the project site, while utilizing all of the General Plan designations.

This alternative would NOT meet the following project objectives (explanations follow each objective and have been *italicized*):

- Provide for the establishment of a master-planned community through implementation of a Specific Plan, consisting of a maximum of 1,329 dwelling units, which is consistent with the scale and character of planned uses in surrounding areas.

Part of this objective would be met in that the City requires a Specific Plan to be prepared for projects over 100 acres. However, the number of dwelling units would be much greater than what is proposed for the project.

- Provide a variety of detached single-family lot sizes in traditional subdivision layouts that are marketable within the evolving economic and demographic profile of the City of San Jacinto.

This alternative could result in only two housing types that utilize the maximum allowable density range.

- Provide public and private recreational amenities for the benefit of residents of this community and of the City of San Jacinto.

The General Plan allows for a variety of recreational uses under the Open Space Recreation designation, but this alternative would not necessarily result in such uses being available to the public.

- Incorporate recycled water from EMWD to supply the lake and irrigate landscaping to minimize the use of potable water.

There is no guarantee that this alternative would accommodate a lake. However, it is likely that any landscaping could use recycled water, thus meeting part of this objective.

- Provide development opportunities for municipal, office, professional, and neighborhood retail commercial land uses within the community to support the economic growth of the City and to reduce the reliance of automobile use within the surrounding community.

This alternative does not allow for development of municipal, office, and professional land uses.

- Establish a circulation system that meets projected traffic volumes and accommodates a variety of transportation modes and encourages alternatives to automobile use within the community.

There is no guarantee that the circulation system associated with this alternative could adequately accommodate the projected increase in traffic volumes.

10.2.3 Reduced Density Alternative

Project Description

This project alternative would involve the development of a low density housing tract with approximately 1-acre lots. Due to drainage and infrastructure needs, this alternative would consist of approximately 350 single-family homes (on approximately 350 acres), 41 acres of parks, 27 acres of greenbelts, 14 acres of drainage basin, 18 acres of lake surfaces, 18 acres of roadways and a 3 acre clubhouse. Due to the existing nature of the site topography, this project alternative would be prepared, graded and designed in a similar fashion as the proposed project.

Environmental Analysis

Landform Alteration and Aesthetics

This alternative would represent a similar change in urban land use as the proposed alternative but would be less intense. This alternative would appear as a developed suburban neighborhood in the western San Jacinto Valley in place of the existing agricultural setting.

Agricultural Resources

This alternative would be similar to the proposed project in that it would eliminate agricultural land use from the project site. This project alternative does not provide for reduced impacts to agricultural resources because it proposes development over the entire site.

Biological Resources

This alternative would result in similar impacts as the proposed project. All significant impacts of the project are mitigated through project-specific mitigation, and therefore the alternative does

not offer mitigation that is necessary to reduce significant impacts to less than significant levels. The project's relationship with the Western Riverside MSHCP would be similar as described for the proposed project.

Geology and Soils

Similar impacts related to seismic hazards would occur under this project alternative. It is anticipated that similar mitigation measures would be imposed and similar to the proposed project, result in all significant impacts being mitigated.

Cultural Resources

Because the presence of undiscovered cultural resources is unknown for both this and the proposed project alternative, risk of significant impacts would be the same as the proposed project. It is anticipated that similar mitigation measures would be imposed as for the proposed project which would result in all significant impacts being mitigated.

Paleontological Resources

Because the presence of paleontological resources is unknown for both this and the proposed project alternative, risk of significant impacts would be the same as the proposed project. It is anticipated that similar mitigation measures would be imposed and would similarly result in all significant impacts being mitigated.

Water Resources and Water Quality

Similar water quality impacts would result under this alternative as described for the proposed project. The project site would likely be susceptible to the same flooding and groundwater hazards as outlined for the proposed project. It is anticipated that application of mitigation measures such as those required of the proposed project would have similar impact reducing effects for this alternative. However, this alternative is not inherently less impactive from a drainage/run-off and urban pollutant perspective than the proposed project due to less intensity of land use. Therefore, it is likely that this project alternative would reduce potential water quality impacts compared to the proposed project.

Transportation, Circulation and Access

Similar to the proposed project, this alternative would likely necessitate reconfiguration of several intersections; however, certain mitigation measures (intersection improvements) may not be necessary due to the elimination of the school, commercial/mixed uses and 666 fewer housing units as compared with the project. While directional splits of traffic for this alternative would be

different than those of the proposed project, this alternative would result in substantially less traffic to surrounding roadways.

Air Quality

Because of the South Coast Air Basin's non-attainment status for several criteria pollutants, air quality impacts, although less in quantity, would still occur under this reduced density scenario. Therefore, this alternative would not substantially reduce impacts to air quality due to fewer mobile source emissions. Short term air quality impacts related to application of architectural coatings could be substantially reduced under this alternative. However, impacts to air quality would likely remain at a significant, unmitigable level due to contribution of long term vehicular emissions.

Noise

The reduction in traffic under this alternative would reduce overall traffic noise anticipated on Sanderson Avenue, Odell Avenue and other nearby streets. While the project itself wouldn't generate as much traffic-producing noise, it is likely that homes along both internal and external roadways would require analysis of anticipated noise levels at property lines, etc. It is therefore assumed that similar noise impacts to future property owners would occur and mitigation measures in the form of set-backs and noise attenuation walls would be necessary to mitigate any noise impact.

Public Services and Utilities

The demand on public facilities such as water and sewer service would be less under this alternative due to a smaller user group at the site. However, no significant impacts were identified for public services and facilities, and therefore, this alternative does not offer any substantial benefits in terms of impact reduction.

Hazards/Risk of Upset

Similar hazards would result under this alternative as anticipated for the proposed project. Hazardous materials would need to be disposed of and any remaining soil hazards remediated. Further, hazards associated with existing cattle raising areas would be the same type as anticipated for the proposed project.

Relationship to Project Objectives

The Reduced Density Alternative WOULD meet the following project objectives:

- Consider topographic, geologic, hydrologic, and environmental opportunities and constraints to create a design which safely accommodates seismic and hydrologic hazards.
- Develop an environment that is visually attractive, efficient, and effectively organized, which includes a pleasing landscape palette.
- Integrate the project with the character of the surrounding community and establish development that results in logical, coordinated growth.
- Establish a circulation system that meets projected traffic volumes and accommodates a variety of transportation modes.
- Provide drought-tolerant and water-efficient landscaping for the community.
- Incorporate recycled water from EMWD to supply the lake and irrigate landscaping to minimize the use of potable water.
- Provide public and private recreational amenities for the benefit of residents of this community and of the City of San Jacinto.
- Provide a system of public and community facilities within residential neighborhoods to support development in an efficient and timely manner.
- Provide a development with unified design elements, such as architecture, landscaping, color palette, paving, walls, fencing, signage, and entry treatments.

This alternative would NOT meet the following project objectives:

- Provide for the establishment of a master-planned community through implementation of a Specific Plan, consisting of a maximum of 1,329 dwelling units, which is consistent with the scale and character of planned uses in surrounding areas.

Part of this objective would be met in that the City requires a Specific Plan to be prepared for projects over 100 acres. However, the number of dwelling units would be much lower than what is proposed for the project.

- Implement housing-type diversity by providing a variety of detached single-family lot sizes in traditional and non-traditional subdivision layouts that offer a wide range of affordability to meet the changing economic and demographic profile of the City of San Jacinto.

This alternative would not meet this objective in that only one housing type would be provided.

- Provide development opportunities for municipal, office, professional, and neighborhood retail commercial land uses within the community to support the economic growth of the City and to reduce the reliance of automobile use within the surrounding community.

This alternative would not meet any of these objectives in that it would not provide any municipal, office, professional or retail commercial land uses.

10.3 COMPARATIVE ANALYSIS

A matrix displaying the major characteristics and significant environmental effects of each alternative is provided in *Table 10.0-1, Alternatives Summary*. The matrix also indicates whether the alternative would be feasible in terms of meeting the project objectives as defined in *Section 3.0, Project Description*, of this EIR.

Table 10.0-1
Alternatives Summary

Environmental Issue	Proposed Project	No Project/No Development	Existing General Plan Designation	Reduced Density
Landform Alteration/ Aesthetics	Mitigable Impacts	Reduced impacts due to lack of changed aesthetic nature	Similar, but does not provide as many transitions between land uses	Similar
Agricultural Resources	Unmitigable Impacts	No Impact	Similar	Similar
Biological Resources	Mitigable Impacts	No Impact	Similar	Similar
Geology and Soils	Mitigable Impacts	No Impact	Similar	Similar
Cultural Resources	Mitigable Impacts	No Impact	Similar	Similar
Paleontological Resources	Mitigable Impacts	No Impact	Similar	Similar
Water Quality/ Hydrology	Mitigable Impacts	No Impact	Similar	Similar but less impervious surface due to less intensity of land use.
Transportation/ Circulation/Access	Mitigable Project Impacts Unmitigable Cumulative Impacts	No traffic impacts, but would not facilitate City's goal of installing infrastructure in western San Jacinto	Similar, but would result in higher traffic volumes that may not be completely mitigated.	Less impacts due to less overall trips
Air Quality	Unmitigable Impacts	No Impact	Greater Impacts	Less impacts but likely still significant and unmitigable due to non-attainment status of basin
Noise	Mitigable Impacts	No Impact	Greater Impacts	Similar

Table 10.0-1 (continued)

Environmental Issue	Proposed Project	No Project/No Development	Existing General Plan Designation	Reduced Density
Public Services/Utilities	Mitigable Impacts	No Impact	Similar, but water use and other utility use would be much higher under this alternative	Less impacts due to less demand for services
Hazards/Risk of Upset	Mitigable Impacts	No Impact	Similar	Similar
Meets Most Project Objectives?	Yes	No	No	No

Environmentally Superior Alternative

CEQA requires that an environmentally superior alternative, other than the No Project Alternative, be identified in an EIR. As shown in *Table 10.0-1*, although the Reduced Density Alternative does not meet most of the project objectives, it would reduce traffic, noise, public services/utilities and air quality impacts when compared to the proposed project. Consequently, this alternative is considered the environmentally superior alternative. That said, as analyzed in this chapter, no substantial advantages are offered by the Reduced Density Alternative when compared to the proposed project since the project would mitigate all significant public services/utilities and noise impacts to less than significant levels. All other impacts associated with the Reduced Density Alternative would be similar to the proposed project, and would require a similar level of mitigation. As with the proposed project, the Reduced Density Alternative would contribute pollutants to the air basin which is currently in non-attainment status, therefore significant, unmitigable air quality impacts would remain. Furthermore the environmentally superior alternative would also contribute to a significant cumulative traffic impact if the MCP and SR-79 improvement projects are not in place when the project is completed.

Executive Summary

Shea Properties Management Company, Inc. (Shea, the User) retained Roux Associates, Inc. (Roux) to perform a Phase I Environmental Site Assessment (ESA) of the property located at west of North Sanderson Avenue, Assessor's Parcel Numbers (APNs) 432-030-006, 432-030-010, and 432-030-011 (the Site). Roux performed this Phase I ESA in general accordance with the American Society for Testing Materials (ASTM) *Standard Practice for Environmental Site Assessments: Phase I Environmental Site Assessment Process* (ASTM E1527-13) in an effort to identify, to the extent feasible, the presence of recognized environmental conditions (RECs) with respect to the Site as defined in ASTM E1527-13. Exceptions to, or deletions from, this practice are described in Section 8.1 of this report.

The Site consists of approximately 470 acres bound by North Sanderson Avenue to the east and is located east of Odel Avenue and south of Ramona Boulevard in a rural and agricultural area of San Jacinto, California. No addresses are currently assigned to the Site; however, 870 and 1380 North Sanderson Avenue have previously been used. Based on a review of historical sources, the Site was developed with a residential structure by 1901 with a workshop and two barns added by 1953. By 1949, the northeastern portion of the Site was developed for agricultural use, possibly row crops. Agricultural production extended to the remainder of the Site and remained until approximately 2012. Agricultural features added to the Site include water wells for domestic and irrigation use and small ponds. By 1978, 20 acres on the southeastern portion of the Site were developed with a heifer raising farm including corrals, water cisterns, and covered structures. A large pond (or water reservoir) was added to the southwestern corner of the Site by 1985. The heifer farm remained operational through at least 2006 became inactive by 2009. All the former structures, including all residential and agricultural support structures were demolished by 2012. The Site has since remained inactive and currently consists of vacant graded land with earthen roads.

On August 3, 2021, Roux visually assessed the Site during the site reconnaissance for potential RECs, including, but not limited to, potential underground storage tanks (USTs), aboveground storage tanks (ASTs), polychlorinated biphenyl (PCB)-containing equipment, hazardous materials storage or handling areas, containerized or bulk wastes, and visual indications of impacted soil.

Roux also performed a records review in an effort to identify RECs in connection with the Site. This records review addressed the Site and surrounding properties. Roux reviewed commercially available records associated with the Site and nearby properties to assess potential concerns associated with the migration of hazardous substances. The records review also included reasonably ascertainable historical data, which can be helpful in identifying the past uses of the Site and surrounding areas, as it may relate to the environmental condition of the Site.

Roux performed interviews and/or file reviews with various government agencies and other parties with possible knowledge of the Site and surrounding properties in an effort to identify current and past uses of the Site and surrounding areas, as they may relate to the environmental condition of the Site.

ASTM E 1527-13 defines a Recognized Environmental Condition (REC) as:

> "The presence or likely presence of any hazardous substances or petroleum products in, on, or at a property: (1) due to release to the environment; (2) under conditions indicative of a release to the environment; or (3) under conditions that pose a material threat of a future release to the environment. De minimis conditions are not recognized environmental conditions."

A Controlled Recognized Environmental Condition (cREC) as:

> "A recognized environmental condition resulting from a past release of hazardous substances or petroleum products that has been addressed to the satisfaction of the applicable regulatory authority (for example, as evidenced by the issuance of a no further action letter or equivalent, or meeting risk-based criteria established by regulatory authority), with hazardous substances or petroleum products allowed to remain in place subject to the implementation of required controls (for example, property use restrictions, activity and use limitations, institutional controls, or engineering controls)."

And a Historical Recognized Environmental Condition (hREC) as:

> "A past release of any hazardous substances or petroleum products that has occurred in connection with the property and has been addressed to the satisfaction of the applicable regulatory authority or meeting unrestricted use criteria established by a regulatory authority, without subjecting the property to any required controls (for example, property use restrictions, activity and use limitations, institutional controls, or engineering controls). Before calling the past release a historical recognized environmental condition, the environmental professional must determine whether the past release is a *recognized* environmental condition at the time the Phase I Environmental Site Assessment is conducted (for example, if there has been a change in the regulatory criteria). If the EP considers the past release to be a recognized environmental condition at the time the Phase I ESA is conducted, the condition shall be included in the conclusions section of the report as a recognized environmental condition."

The term recognized environmental condition is not intended to include de minimis conditions that generally do not present a threat to human health or the environment and that generally would not be the subject of an enforcement action if brought to the attention of appropriate governmental agencies.

This Executive Summary provides a brief overview of the findings of this Phase I ESA. Although the Executive Summary is an integral part of a report, it does not substitute for reading the entire report or the appended or referenced documents in order to fully understand the findings and potential environmental concerns associated with the Site.

Based on the information obtained through the performance of this ESA, Roux identified the following RECs in connection with the current and historical operations at the Site or adjacent properties. To the extent possible, the locations of the RECs are shown in Figure 2. To avoid confusion, all RECs, cRECs, hRECs, and OEFs are numbered sequentially.

REC 1 – Former Heifer Farm. A southeastern portion of the Site, totaling approximately 20 acres in size, was formerly developed as a heifer raising farm from at least 1978 through 2002. The former heifer farm operations represented a REC due to the possible presence of methane from manure.

REC 2 - Petroleum-Stained Soil. During a reconnaissance of the Site conducted in 2002, petroleum-stained soil was observed beneath a diesel aboveground storage tank (AST) located northwest of the reservoir (pond), near the irrigation groundwater well located southwest of the reservoir, and on the floor of the equipment shed, beneath three oil-containing 55-gallon drums. Based on the storage of hazardous substances and petroleum products in uncovered ground areas and evidence of a release, the former chemical storage identified above represented a REC.

REC 3 - Pond. The Site is equipped with a pond located on the southwestern corner. According to aerial photographs, the pond was added between 1978 and 1985 and was likely used as part of the heifer ranch operations. According to a 2009 Environmental Impact Report (EIR), the reservoir contained reclaimed water from the neighboring San Jacinto Valley Regional Water Reclamation Facility related to irrigation for sod farming activities on-Site. It is unknown whether the pond also historically received wastewater from the on-Site ranch operations, was used for agricultural irrigation, or stored water treated with larvicide/repellant for mosquito control. The pond appeared unlined, allowing waters to infiltrate the ground and recharge the aquifer. Based on the historical agricultural use of the Site, the on-Site pond represents a REC.

REC 4 - Former Agricultural Applied Pesticide Area. Based on a review of historical sources, a portion of the Site was developed for agricultural use (row crops) as early as 1949 with increased agricultural development noted from at least 1978 to 2016. No indications of former row crops were observed on the Site. According to the EIR, a portion of the Site was developed as a sod farm from 1997 through at least 2002. Any residual pesticide, herbicide, or fertilizer residue in Site soils associated with sod farming was not identified as an environmental concern based on the removal of shallow soils during sod harvest. Agricultural production prior to 1997 at the Site is not currently known. However, it is likely that agricultural chemicals, such as pesticides, herbicides, and fertilizers, were used on-Site historically, and the potential for impacts from agricultural chemicals to on-Site soils is considered a REC.

Roux did not identify known or suspected cRECs in connection with the current and historical operations at the Site or adjacent properties.

Roux identified the following hRECs in connection with the current and historical operations at the Site or adjacent properties.

hREC 5 – Historical Underground Storage Tanks. Westra Dairy Farm, formerly located on-Site at 870 Sanderson Avenue, was identified as having a closed Leaking Underground Storage Tank (LUST) file. According to closure documents, the former on-Site dairy farm (or heifer ranch) had two 1,000-gallon gasoline USTs and one 10,000-gallon gasoline UST located south of a former workshop building in the southern portion of the Site. All three USTs were removed from the Site in December 1999 under direction of the County of Riverside. The tank area was over-excavated and approximately 120 tons of contaminated soil were removed and transported for off-Site disposal. In October 2000, a soil investigation identified total petroleum hydrocarbon (TPH) and volatile organic compounds (VOC) impacts below the former tanks to a depth of 35 feet bgs. In May 2001, a vapor extraction well was subsequently in the vicinity of the former tanks and a mobile soil vapor extraction system was used to extract and treat soil vapor. Soil samples do not appear to have been collected following the vapor extraction test. It is unknown if the SVE system operated outside of the 7-hour vapor extraction test as part of remediation for the impacted soils. A “No Further Action” letter was issued by the Santa Ana Regional Water Quality Control Board (SA-RWQCB) to the Westra Family Trust on December 26, 2001. The closure letter recommended that correction action should be reviewed if land use changes. According to the “No Further Action” letter, data from this investigation indicates that the residual petroleum hydrocarbons in soil are limited to an area with a 15-foot radius between 15 and 20 feet bgs and did not indicate a significant presence or source of petroleum hydrocarbons in the soil. Although a closure document was issued by the SA-RWQCB in 2001, the remaining petroleum hydrocarbon-impacted soil in the former LUST area is considered a hREC.

The term recognized environmental condition is not intended to include de minimis conditions that generally do not present a threat to human health or the environment and that generally would not be the subject of an enforcement action if brought to the attention of appropriate governmental agencies. Other environmental features (OEFs) are environmental conditions that do not meet the definition of a REC, but which may warrant mention in a comprehensive Phase I ESA. Based on the subject Phase I ESA, Roux identified the following OEFs. To the extent possible, the locations of the OEFs are shown in Figure 2.

OEF 6 - Septic Systems. According to the EIR, the Site was equipped with two septic systems that historical sources suggest may have been in operation for many decades. The EIR stated the septic systems would be removed along with any residue material in accordance with Riverside County Department of Environmental Health (RCDEH) protocols. Based on the likely use of these systems for domestic waste only, the existing septic systems represent an OEF.

OEF 7 - Debris. Debris, including old equipment, water heaters, tires, and trash were observed in several piles throughout the site both in the 2002 Phase I ESA and during Site reconnaissance associated with the EIR. Several mounds of soil also were observed across the Site. According to the EIR, the soil piles were generated from on-Site activities and were piled for storage and eventual removal. The EIR recommended a qualified environmental professional be present on-Site during removal of debris piles to assess debris and stockpiled soils and direct disposal accordingly. Based on observations made during the Site reconnaissance, on-Site debris represent an OEF.

OEF 8 - Abandoned Drums. Two abandoned 55-gallon drums were observed during Roux' Site reconnaissance on August 3, 2021. The drums were observed on a concrete pad in the southeastern portion of the Site in the vicinity of the former heifer ranch area and appeared to contain unknown waste products. Minor to moderate staining was observed in the vicinity of these features. The staining was located on a paved area. It appears that the staining is surficial in nature and thus is not expected to represent a significant environmental concern.

1. Introduction

Roux Associates, Inc. (Roux) completed this Phase I Environmental Site Assessment (ESA) of the commercial property located at west of North Sanderson Avenue (the Site). The Site location is shown in Figure 1 and the Site and vicinity is shown in Figure 2. Roux performed this Phase I ESA in compliance with the scope and limitations of American Society for Testing Materials (ASTM) E1527-13 and the terms and conditions of Roux' proposal dated August 19, 2021. Roux conducted this Phase I ESA for the benefit of Shea Properties (Shea, the User).

The following sections of this report present our Phase I ESA findings and conclusions. A glossary containing terms and definitions presented in ASTM E1527-13 is included in Appendix A – Glossary of Terms. Other appendices presented at the end of the report include historical topographic maps, historical aerial photographs, regulatory records review documentation, applicable historical records, and personnel qualifications.

1.1 Purpose

The purpose of this Phase I ESA is to identify and report, to the extent feasible, recognized environmental conditions (RECs) with respect to the Site. Performing a Phase I ESA in general compliance with ASTM E 1527-13 may enable a User to satisfy one of the requirements to qualify for the innocent landowner, contiguous property owner, or bona fide prospective purchaser limitations on Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) liability. That is, the practice that constitutes one of the requirements for "all appropriate inquiry into the previous ownership and uses of the property consistent with good commercial or customary practice" as defined in 42 USC Section 9601(35) (B).

1.2 Scope of Services

The scope of services for this Phase I ESA included, but was not limited to, the activities listed below.

- A review of reasonably ascertainable and practicably reviewable topographic maps, historical aerial photographs, and city directories, if available, to investigate past Site conditions;
- A review of specific government lists pursuant to ASTM Standard E 1527-13 regarding environmental activities for the Site and local area properties;
- A review of recorded land title records, building, assessors, and fire department records, for permits, citations, and reports connected to the Site that were reasonably ascertainable, practicably reviewable, and publicly available within reasonable time and cost;
- An inspection by an environmental professional to investigate the current use of the Site and to identify environmental concerns including but not limited to, the presence of hazardous substances or petroleum products, wastes, underground storage tanks (USTs), aboveground storage tanks (ASTs), or other environmental concerns;
- Interviews with available representatives of the owner of the Site, occupants, and local government officials by an environmental professional; and
- Preparation of this Phase I ESA report.

Roux initiated this Phase I ESA pursuant to receipt of written authorization to proceed on August 26, 2021.

1.3 Standard of Care

Roux conducted this Phase I ESA using a defined scope of services considered appropriate and agreed upon by all parties on the date the service was authorized, unless the scope of services or the methods used were later modified, in writing, and accepted by all parties prior to performance. Roux conducted this Phase I ESA in accordance with generally accepted practices in a manner consistent with that level of care exercised by other members of our profession in the same locality and under similar conditions of time and accessibility of improvements and information. No other representations, expressed or implied, and no warranty or guarantee is included or intended to be part of this Phase I ESA.

Please note that the scope of services performed in execution of this assessment may not be appropriate to satisfy the needs of other parties. We, therefore, are not responsible for independent conclusions, opinions, or recommendations of others based on our assessment. Furthermore, this Phase I ESA relates to the environmental conditions of the Site and does not address issues raised in transactions such as business risk, purchase of business entities, or interests therein, or of their assets, that may well involve environmental liabilities pertaining to properties previously owned or operated or other offsite liabilities.

Additionally, the findings of this Phase I ESA are based on Roux' observations, inquiries, and historical research using reasonably ascertainable and practically reviewable information obtained within reasonable time and cost constraints. Roux does not represent that this Phase I ESA is an exhaustive investigation that reflects the findings of all of the information available for the Site, nor is it representative of future Site conditions. If additional information is generated from the Site, it should be provided to Roux so that we may evaluate its impact on our conclusions. As such, activities or episodes that transpire subsequent to this Phase I ESA are not considered in this assessment. It is not intended that a Phase I ESA in accordance with ASTM E1527-13 be an exhaustive assessment of a property nor can it wholly eliminate uncertainty regarding the potential for *recognized environmental conditions* in connection with a property.

1.4 Assumptions

This Phase I ESA Report, including the exhibits attached hereto, describes the results of Roux' investigation to identify the presence of *recognized environmental conditions* connected with the Site in accordance with ASTM E1527-13, as allowed by and consistent with the regulatory requirements of the All Appropriate Inquiry Rule, 40 CFR Part 312, Amendment to Standards and Practices for All Appropriate Inquires Under CERCLA, Final Rule, published December 30, 2013 (AAI Rule). Specifically, the preamble to the amended AAI Rule states:

> *The Environmental Protection Agency (EPA) today is taking final action to amend the standards and practices for conducting all appropriate inquiries under the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) to reference a standard practice recently made available by ASTM International, a widely recognized standards development organization. Specifically, this final rule amends the "All Appropriate Inquiries Rule" at 40 CFR Part 312 to reference ASTM International's E1527–13 "Standard Practice for Environmental Site Assessments: Phase I Environmental Site Assessment Process" and make clear that persons conducting all appropriate inquiries may use the procedures included in this standard to comply with the All Appropriate Inquiries Rule*[1].

[1] Federal Register: December 30, 2013 (Volume 78, Number 250) Page 79319

One of the requirements that a person acquiring real property must meet in order to qualify for either the innocent landowner, contiguous owner, or bona fide prospective purchaser (collectively hereinafter "Prospective Purchaser") defense to liability under the federal Comprehensive Environmental Response, Compensation, and Liability Act of 1980, as amended by the Superfund Amendments and Reauthorization Act of 1986, and the Small Business Liability Relief and Brownfields' Revitalization Act of 2002, 42 U.S.C. 9601-9675 (collectively referred to hereafter as "CERCLA") is that person must conduct all appropriate inquiries into the previous ownership and uses of the property in conformance with the AAI Rule (or the ASTM E1527-13) prior to acquisition of the property. The User has acknowledged that, under the AAI Rule, Roux' performance of this Phase I ESA in accordance with ASTM E1527-13 will not alone result in the User satisfying all requirements of the AAI Rule and will not in itself provide a defense to CERCLA liability. The User has acknowledged that the AAI Rule also requires that the Prospective Purchaser undertake certain additional inquiries and post-acquisition activities to satisfy the CERCLA AAI requirements. Accordingly, Roux makes no guarantees or warranties, expressed or implied, regarding this Phase I ESA, including without limitation, that this Phase I ESA will qualify the User for a defense to CERCLA liability.

Roux has performed this Phase I ESA in a professional manner using that degree of skill and care exercised for similar projects under similar conditions by reputable and competent environmental consultants. Professional judgments expressed herein are based on the facts currently available to Roux.

The AAI Rule requires, and the conclusions and recommendations stated herein represent, the application of a variety of engineering and technical disciplines to material facts and conditions associated with the Site. As such, these conclusions and recommendations are based on subjective interpretations and the exercise of discretion based on the facts available to Roux and conditions at the time of the performance of this Phase I ESA. Many of these facts and conditions are subject to change over time. Accordingly, the conclusions and recommendations must be considered within this context.

The User has agreed that Roux shall not be responsible for conditions or consequences arising from relevant facts that were concealed, withheld, or not fully disclosed at the time this Phase I ESA was performed. To the extent practicable, Roux has identified data gaps, and has evaluated the potential significance of such data gaps. Recommendations to address those data gaps are presented herein and are based on the data available at the time of the performance of this Phase I ESA. Implementation of the recommendations may not fully address the data gaps, and the information obtained from execution of those recommendations may alter and/or modify the interpretation of the Site conditions and conclusions, herein. This Phase I ESA does not include consideration of matters specifically excluded by ASTM E1527-13, including but not limited to, asbestos-containing building materials, radon, lead-based paint, lead in drinking water, wetlands, regulatory compliance, and mold unless specifically identified herein.

Roux has not collected any soil and/or groundwater samples on the Site for Phase I purposes, and is relying on information presented by others, often in preliminary, draft, or verbal form. By referencing this information, Roux does not accept responsibility for the accuracy of the underlying data, sampling methods, laboratory analysis, or documentation.

This Phase I ESA Report should not be considered a legal interpretation of existing environmental laws and regulations. This Phase I ESA was conducted with a reasonable degree of inquiry to identify *recognized environmental conditions*, but uncertainty is not eliminated. No Phase I ESA can wholly eliminate uncertainty regarding the potential for *recognized environmental conditions* in connection with a property.

The Phase I ESA process is intended to reduce, but not eliminate, the uncertainty involved with identifying *recognized environmental conditions*.

This Phase I ESA Report is not an appraisal or value judgment of the Site. The User has agreed that Roux shall not be liable for any use of this Phase I ESA Report as an appraisal or value judgment of the Site.

This Phase I ESA Report has been prepared for the exclusive use of the User for specific application to the Site covered by this Phase I ESA Report. The User has agreed that any third-party use of this Phase I ESA Report, upon disclosure by the User, is the sole responsibility and at the sole liability of the User.

1.5 User Reliance

No additional parties may use the information contained in this report without obtaining the written permission of Roux or the User. Roux' duties and obligations extend to the User and to no other party. Roux' duties and obligations to the User are not transferable to persons, corporations, or organizations without the express written consent of the User and Roux. The User may rely upon the information provided in this Phase I ESA report for a period of 180 days from the date of issue. After 180 days, this Phase I ESA should be updated in accordance with ASTM guidance. Roux will not be liable for any consequential damages arising from the use of this report for other than its intended purpose, for use of this report beyond 180 days of its issue date, or from unauthorized use by third parties.

This Phase I ESA report must be read and interpreted as a whole and can only be considered representative of the conditions of the Site as of the date of our site reconnaissance described herein. Roux makes no representation whatsoever concerning the condition of the Site beyond the date of our site reconnaissance described herein. Individual sections and appendices of this report are dependent on the balance of this report, and on the terms, conditions, and stipulations contained in the proposal and written amendments accepted by Roux.

2. Site Description

2.1 Site Location and Description

Site Information	
Site Name	Shea San Jacinto
Street Address(es)	No current address; Historically used 870 and 1380 North Sanderson Avenue
City	City of San Jacinto
County	Riverside
State	California
Location	West of North Sanderson Avenue, east of Odel Avenue and south of Ramona Boulevard
Assessor's Parcel Number (APN)	432-030-006, 432-030-010, and 432-030-011
Site Acreage (per Riverside County Assessor Website)	Approximately 470 acres
Site Occupant(s)	None; currently unoccupied
Onsite Operations	None; formerly operated as sod farm and heifer raising farm
Description of Onsite Structures	None; Site consists of vacant land and is equipped with remnant cisterns, concrete building foundations, and a pond (water reservoir)
Site Paving	Unpaved vacant graded land with areas overgrown with weeds and native desert brush
Site Grading	Graded to drain at a gentle slope roughly oriented to the north
Site Vicinity	Rural and agricultural

Refer to Section 5.0 for a detailed description of the current condition of the Site and operations.

2.2 Vicinity General Characteristics

The facilities and improvements which are located immediately adjacent to the Site are provided in the following table.

Direction from Site	Improvements / Use (Addresses)
North	Records Road and vacant and/or agricultural land
East	North Sanderson Avenue, followed by vacant and/or agricultural land and California Equine Retirement Foundation (805 North Sanderson Avenue)
South	San Jacinto Valley Regional Water Reclamation Facility (770 North Sanderson Avenue)
Southwest	Residence and vacant and/or agricultural land
West	Demler Farms (1455 North Warren Road)

2.3 Past Use of the Site

Based on a review of historical sources, the Site was developed with a residential structure by 1901 with a workshop and two barns added by 1953. By 1949, the northeastern portion of the Site was developed for agricultural use, possibly row crops. Agricultural production extended to the remainder of the Site and remained until approximately 2012. Agricultural features added to the Site include water wells for domestic and irrigation use and small ponds. By 1978, 20 acres on the southeastern portion of the Site were developed with a heifer raising farm including corrals, water cisterns, and covered structures. A large pond (or water reservoir) was added to the southwestern corner of the Site by 1985. The heifer farm remained operational through at least 2006 became inactive by 2009. All the former structures, including all residential and agricultural support structures were demolished by 2012. The Site has since remained inactive and currently consists of vacant graded land with earthen roads.

2.4 Physical Setting

Roux obtained and reviewed published, reasonably ascertainable information concerning the physical setting of the Site. The following is a summary of the information reviewed from those physical setting sources.

Physical Setting Summary	
United States Geological Survey (USGS) Topographic Map	Lakeview, California Quadrangle
Approximate Site Elevation / Source	1460 to 1490 feet above mean sea level (msl) / Lakeview, California (2012) 7.5-minute quadrangle topographic map published by the USGS
Nearest Surface Water Features / Approximate Distance	San Jacinto Reservoir, an unlined stormwater drainage pond / 0.3 mile east of the Site
Regional Geology / Source	Quaternary deposits: alluvium, lake, playa and terrace, consolidated and semi-consolidated / California Department of Conservation, 2010 Geologic Map of California
Site Topography / Source	Generally flat with a gradual slope to the east-northeast / Site observation and USGS topographic map
Hydrogeological Region / Source	Located along the eastern portion of the San Jacinto Groundwater Basin / *California Department of Water Resources Bulletin 118, Update 2003 and Interim Update 2016*
Depth to Groundwater / Source	Greater than 70 feet bgs / Previous Site investigation (ATC, 2000) 11 to 13 feet bgs (perched) / Monitoring well installation report for a facility approximately 0.6 mile northeast of the Site (Leighton, 2009)
Groundwater Gradient Direction / Source	Northeast / Groundwater monitoring data for a facility approximately 0.6 mile northeast of the Site (Leighton, 2009)
Onsite Soil	Unconsolidated sands and gravel from the surface to 70 feet bgs (ATC, 2000)

3. Sources of Information

Sources of information utilized in preparing this Phase I ESA report included historical topographic maps; historical aerial photographs; a walkover survey of the Site and adjoining properties; in-person discussions with User and tenant personnel; a review of records available at selected local and state regulatory agencies; a review of databases maintained by local, state, and federal government agencies; and other records available from commercial and online sources.

3.1 Historical Sources

To help understand the history of the Site and past land uses, historical sources were obtained from Environmental Data Resources, Inc. (EDR), of Shelton, Connecticut. The sources and locations within the Appendices are provided in the table below.

EDR Historical Sources		
Historical Range	**Source**	**Appendix**
1901 - 2012	U.S. Geological Survey Topographic Maps	B
1938 - 2016	EDR Aerial Photographs “Decade Package”	C
No Available Coverage	EDR “Certified Sanborn® Map Report”	D
1971 - 2017	EDR “City Directory Image Report”	E

3.2 Site Reconnaissance

On August 3, 2021, Roux personnel conducted a reconnaissance of the Site and surrounding areas. Roux visually and/or physically observed adjoining properties from reasonably accessible locations on the Site and public thoroughfares. Photographs documenting Roux’ Site Reconnaissance are provided in Appendix G.

3.3 Regulatory Agencies

Roux contacted governmental agencies for reasonably ascertainable information concerning environmental conditions at the Site. Roux contacted or reviewed information from the agencies provided in the following table. Refer to Appendix G – Pertinent Historical Documentation for copies of the records reviewed. A summary of the information gathered from the regulatory agencies is provided in the table and details regarding the records were incorporated into applicable sections as noted.

Agency	Date Requested / Accessed	Response Date	Description of Records	Section Discussed
Federal				
U.S. Environmental Protection Agency (EPA) – FOIAonline	07/29/2021	08/02/2021	No records were associated with the Site	N/A
U.S EPA MyProperty Database	07/29/2021	N/A	No records were associated with the Site.	N/A
National Pipeline Mapping System (NPMS) Online Database	07/29/2021	N/A	No records were associated with the Site.	N/A
State				
State Water Resources Control Board (SWRCB): GeoTracker Online Database	07/29/2021	N/A	A LUST case at Westra Dairy Farm in 2001 was associated with 870 N Sanderson Avenue.	6.0
SWRCB: Storm Water Multiple Application and Report Tracking System (SMARTS) Online Database	07/29/2021	N/A	No records were associated with the Site.	N/A
Department of Toxic Substances Control (DTSC)	07/29/2021	07/30/2021	No additional records were identified through this request – the DTSC referred to available documents on EnviroStor and the HWTS database	N/A
DTSC: EnviroStor Online Database	07/29/2021	N/A	A listing for the proposed high school as associated with the Site. Representatives from the DTSC Cypress office informed Roux any records for the proposed high school not available online are no longer on file and have likely been purged.	8.1
DTSC: Hazardous Waste Tracking System (HWTS) Online Database	07/29/2021	N/A	One disposal record associated with the Western Family Trust is associated with 870 N Sanderson Avenue. This listing appears to be associated with removal of former underground tanks at the Site.	6.0

Agency	Date Requested / Accessed	Response Date	Description of Records	Section Discussed
California Air Resources Board (CARB)	07/29/2021	08/02/2021	No records were associated with the Site.	N/A
California Office of Environmental Health Hazard Assessment (OEHHA)	07/29/2021	N/A	No response has been received as of this report date.	N/A

City / Local				
City of San Jacinto City Clerk	07/29/2021	8/25/2021	Records have not been received as of this report date. According to the City Clerk's office, the request for records is still being processed.	N/A

3.3.1 California Department of Toxic Substances Control (DTSC)

A 61-acre portion of the Site is listed by the California DTSC as the "Proposed High School at the Villages of San Jacinto" (Global ID T60000906) at the intersection of Ramona Boulevard and Cawston Avenue. In 2008, the San Jacinto Unified School District filed for an Environmental Oversight Agreement with the DTSC for oversight of the preparation of a Preliminary Endangerment Assessment (PEA) at Site Assessor Parcel Numbers 432-030-006 and 432-030-010. Three pages of the PEA including the introduction and part of the executive summary are available on EnviroStor appended to a response to comments matrix; however, the full PEA document is not available online. According to the available PEA sections, soil samples were collected and analyzed for organochlorine pesticides and arsenic. The DTSC issued an Approval of PEA Report on September 17, 2008, and stated that neither a release of hazardous material nor the presence of a naturally occurring hazardous material posed a threat to public health or the environment. The case is currently marked as 'No Further Action' on EnviroStor as of September 24, 2008. According to EnviroStor records, the area assessed was limited to 61 acres that were planned for school redevelopment. Soil sampling for pesticides and metals does not appear to have been conducted on the remaining areas of the Site.

Roux contacted the DTSC Cypress office for copies of the PEA reports. Ms. Gloria Conti and Ms. Jone Barrio of the DTSC Cypress office informed Roux that no other pertinent records, including the PEA report, for the proposed high school are on file with the DTSC and have likely been purged. Ms. Jone Barrio informed Roux that a copy of an Environmental Impact Report (EIR) is available for review in the DTSC file room. Roux' inability to obtain a copy of the previous PEA report represents a data gap. Based the limited information available online for the PEA and NFA letter issued by the DTSC, this limitation is not expected to alter the findings of this assessment

3.4 Government Databases

To document potential sources of contamination at or near the Site, a government records search was conducted by EDR. The search included local, state, and federal records for the Site and for other properties within ASTM-standard distances of the Site. The records search is summarized in Section 7.0 and a copy of "The EDR Radius Map™ Report with GeoCheck®," dated July 30, 2021, is included in its entirety as Appendix F. As recommended by ASTM, all but a few of the databases searched were "current," i.e., had been updated within 90 days prior to the search date.

3.5 User Provided Information

ASTM E1527-13 provides that the User perform certain tasks. The purpose of this section is to present select User-provided information that can assist in identifying possible *recognized environmental conditions* in connection with the Site. According to ASTM E1527-13, these tasks do not require the technical expertise of an environmental professional and the environmental professional generally does not perform these tasks. Roux administered a questionnaire to the User at the beginning of this Phase I ESA to assist them with these tasks. The following sections outline the parts of the questionnaire that the User completed.

3.5.1 Environmental Liens or Activity and Use Limitations

The User indicated that they have no knowledge regarding environmental liens or activity and use limitations (engineering/institutional controls) with respect to the Site.

3.5.2 Specialized Knowledge

The User did not report any specialized knowledge related to the Site.

3.5.3 Valuation Reduction for Environmental Issues

The User indicated that they have no knowledge regarding valuation reduction for environmental issues.

3.5.4 Commonly Known or Reasonably Ascertainable Information

The User did not have any knowledge regarding commonly known or reasonable ascertainable information about the Site not otherwise addressed.

3.5.5 Obvious Indicators of the Presence or Likely Presence of Contamination of the Site

The User did not have any knowledge regarding obvious indicators of the presence or likely presence of contamination of the Site not otherwise addressed.

3.6 Interviews

On August 26, 2021, Roux attempted to reach an owner of the Site, Mr. Cal Westra, via telephone. Roux was informed that the phone number for Mr. Westra had been reassigned. Based on the information obtained from previous reports and historical sources available, this limitation is not expected to significant alter the findings of this assessment.

4. Site History

This section documents the history of the Site and describes current conditions and existing or former environmental features.

4.1 Site History

The history of the Site and, to a lesser extent, the surrounding area, including previous land use, has been compiled based on information from the exhaustive list of sources provided in Section 3.

Summary of Historical Sources				
Decade	**Year**	**Source**	**Site Description**	**Vicinity Description**
Early Residential Development				
Pre-1900	No Sources Available			
1900s	1901	Historical Topographic Map: Elsinore / San Jacinto (15-minute)	Mostly vacant land located in a rural area of San Jacinto Viejo. Southern portion of the site is developed with a road and single structure likely used as a residence or homestead.	Adjacent sites appear as vacant land. Nearby arterial roads are to the west and north. Two unnamed streams are to the north.
1910s	No Sources Available			
1920s	No Sources Available			
1930s	1938	EDR Aerial Photograph	No significant changes from prior Site history except for addition of ancillary structures to residence or homestead on the southern portion of the Site.	No significant changes from prior history.
Agricultural Development				
1940s	1943	Historical Topographic Map: Perris / Banning (15-minute)	No significant changes from prior Site history.	No significant changes from prior history.
	1949	EDR Aerial Photograph	The northeastern portion of the Site was developed for agricultural use, possibly row crops. Three additional structures were added west of the existing residence in the southern portion and one small structure of unknown use was added on the northwestern corner of the Site	Agricultural development is noted to the northeast and east of the Site.

Summary of Historical Sources				
Decade	**Year**	**Source**	**Site Description**	**Vicinity Description**
1950s	1953	EDR Aerial Photograph	Agricultural development has extended to the northern and central portions of the Site.	Increase agricultural development to the northeast and east of the Site.
		Historical Topographic Map: La Jolla (15-minute)	Three water wells, likely used for irrigation, were added to the Site.	Addition of unnamed road (later Sanderson Avenue) to the east and San Jacinto Reservoir and canal further to the southeast.
1960s	1961	EDR Aerial Photograph	Agricultural development throughout the Site increased.	No significant changes from prior history.
	1967	Historical Topographic Map: Lakeview / San Jacinto (7.5-minute)	A fourth water well and two intermittent ponds were added to the Site.	Addition of duck ponds to the northeast and east, sewage disposal ponds to the south, several wells throughout the surrounding areas, and canal and aqueduct part of the nearby San Jacinto Reservoir.
1970s	1975	EDR Aerial Photograph	The two previous ponds were no longer present. Two windmills were depicted to the west of the Site in topographic maps, although no windmills were noted within the Site boundaries during review of historical aerial photographs	Addition of water reclamation plant adjacent to the south
	1978	EDR Aerial Photograph	A heifer farm, totaling approximately 20 acres, was operating on the southeastern portion of the Site. Discernable features include multiple enclosures (or corrals), and four covered structures.	Addition of ponds or other water features to the southwest and south.
	1979	Historical Topographic Map: Lakeview / San Jacinto (7.5-minute)	No significant changes from prior Site history.	No significant changes from prior history.
1980s	1985	EDR Aerial Photograph	A presently existing water reservoir had been constructed in the southwestern corner of the Site. The remainder of the Site is developed for agricultural use including row crops or heifer farm.	Addition of dairy farms to the west.
	1989	EDR Aerial Photograph	No significant changes from prior Site history.	No significant changes from prior history.
1990s	1991	Building Permits	Site equipped with a residence, workshop, two barns, several corrals, and shade structures. The southern and central portions of the site were used for grain storage (or growth), oats, and alfalfa.	N/A

Summary of Historical Sources				
Decade	**Year**	**Source**	**Site Description**	**Vicinity Description**
	1996	EDR Aerial Photograph	No significant changes from prior Site history.	No significant changes from prior history.
2000s	2002	EDR Aerial Photograph	No significant changes from prior Site history.	No significant changes from prior history.
		Previous Reports	Site was reportedly occupied by one residential structure, two warehouses, a storage shed, two office trailers, and three groundwater wells (one domestic and two irrigation), covered areas for the cows (barn structures), and equipment storage areas	N/A
	2006	EDR Aerial Photograph	No significant changes from prior Site history.	Former ponds to the southwest have been redeveloped for agricultural use (row crops).
	2009	Previous Reports	A site visit was conducted in May 2009 as part of the EIR. The only reported structures observed on-Site were an abandoned residence and “shade structures”. The heifer farm operations were reportedly no longer active as of 2009.	N/A
		EDR Aerial Photograph	Two of the previous “shade structures” remain onsite. The majority of the Site appears vacant and may have no longer been developed for agricultural use.	No significant changes from prior history.
2010s	2012	Historical Topographic Map: Lakeview / San Jacinto (7.5-minute)	No significant changes from prior Site history.	No significant changes from prior history.
		EDR Aerial Photograph	All the former structures have been demolished. Some agricultural features (light row crops) appear throughout the Site.	No significant changes from prior history.
2020s	2021	Site Reconnaissance	No significant changes from prior Site history.	No significant changes from prior history.

5. Current Site Conditions

A Roux representative, Mr. Connor Moore, conducted a reconnaissance of the Site and surrounding areas on August 3, 2021. Roux also visually and/or physically observed adjoining properties from reasonably accessible locations on the Site and public thoroughfares. During the Site reconnaissance, the weather was clear and the temperature was approximately 115° Fahrenheit. A photographic log summarizing the Site Reconnaissance is provided as Appendix G. The following sections summarize observations during the inspection.

5.1 Site Reconnaissance

The Site consists of approximately 470 acres of vacant land and is bound by North Sanderson Avenue to the east and is located east of Odel Avenue and south of Ramona Boulevard. No addresses are currently assigned to the Site; however, 870 and 1380 North Sanderson Avenue have previously been used for two of the parcels. The Site is undeveloped apart from unpaved farm roads and consists of vacant graded land. Graded areas across the Site are overgrown with weeds and native desert brush vegetation and do not appear to have been used for any purpose for many years.

Roux observed the Site from accessible road throughout the Site. Due to the size of the property and the vegetation present on site, isolated areas of the site may have not been accessible for direct observation during the Site reconnaissance.

5.2 Phase I ESA Observations

During Site reconnaissance, Roux personnel attempt to identify any environmental features that may be relevant in the context of the Phase I ESA. The features identified are summarized in the table below. Any such features are discussed in the following subsections.

Feature	Observed on the Site	Observed on an Adjacent Property
Areas of stressed vegetation		
Areas which receive flood or storm water from potentially contaminated areas		
Air Compressor Vent Discharges		
Chemical Storage and/or Use		
Drainage Swales and Culverts		
Discharge Areas		
Discolored or Spill Areas		
Drums (55 Gallons or Larger)	X	
Electrical Transformers	X	
Former Agricultural Applied Pesticide Area	X	

Feature	Observed on the Site	Observed on an Adjacent Property
Hydraulic Lifts		
Incinerators		
Landfills or Landfarms		
Loading and Unloading Areas		
Non-Contact Cooling Water Discharge		
Oil-Water Separator(s)		
Open Areas Away from Production Areas		
Process Area Sinks and Piping		
Rail Cars/Railroad Spurs		
Septic Systems Leach Fields or Seepage Pits		
Silos		
Sprayfields		
Storm Sewer and Spill Containment Collection System		
Storm Water Detention Pond	X	
Surface Impoundments and Lagoons		
Underground / Aboveground Storage Tanks and Associated Piping		
Waste Piles	X	
Wells	X	

5.2.1 Drums (55 Gallons or Larger)

Two abandoned 55-gallon drums were observed during Roux' Site reconnaissance on August 3, 2021. The drums were observed on a concrete pad in the southeastern portion of the Site in the vicinity of the former heifer ranch area and appeared to contain unknown waste products. Minor to moderate staining was observed in the vicinity of these features. The staining was located on a paved area. It appears that the staining is surficial in nature and thus is not expected to represent a significant environmental concern. As a best management practice, any abandoned drums should be removed from the Site and properly disposed.

5.2.2 Electrical Transformers

Roux personnel observed pole-mounted transformers at the Site. Staining was not observed at the base of the transformer poles. Based on the construction and appearance of the transformers, they did not appear to be wet-type, with the potential to contain PCBs. Roux does not consider the presence of these transformers to be an environmental concern.

5.2.3 Former Agricultural Applied Pesticide Area

Based on a review of historical sources, a portion of the Site was developed for agricultural use (row crops) as early as 1949 with increased agricultural development noted from at least 1978 to 2016. No indications of former row crops were observed on the Site. According to the EIR, a portion of the Site was developed as a sod farm from 1997 through at least 2002. Any residual pesticide, herbicide, or fertilizer residue in Site soils associated with sod farming was not identified as an environmental concern based on the removal of shallow soils during sod harvest. Agricultural production prior to 1997 at the Site is not currently known. However, it is likely that agricultural chemicals, such as pesticides, herbicides and fertilizers, were used on-Site historically, and the potential for impacts from agricultural chemicals to on-Site soils is considered a REC.

5.2.4 Storm Water Detention Pond

The Site is equipped with a drainage pond located on the southwestern corner. According to aerial photographs, the pond was added between 1978 and 1985 and was likely used as part of the heifer ranch operations. According to the EIR, the reservoir contained reclaimed water from the nearby San Jacinto Valley Regional Water Reclamation Facility related to irrigation for sod farming activities on-Site. It is unknown whether the pond also historically received wastewater from the on-Site ranch operations, was used for agricultural irrigation, or stored water treated with larvicide/repellant for mosquito control. The pond appeared unlined, allowing waters to infiltrate the ground and recharge the aquifer. Based on the historical agricultural use of the Site, the on-Site pond represents a REC.

5.2.5 Wells

According to topographic maps, the Site has been equipped with at least four groundwater wells located throughout the Site. During the 2002 Phase I ESA, a total of three wells, including one domestic production well and two irrigation wells, were observed on-site. Only one of the three wells noted during the 2002 Phase I ESA match a known well depicted in topographic maps. Two of the irrigation groundwater wells noted during the 2002 Phase I ESA were located during Roux' Site reconnaissance. According to the EIR, any known and discovered wells will be abandoned and decommissioned in accordance with SA-RWQCB and RCDEH protocols.

5.3 Vapor Intrusion

Roux performed a vapor migration/intrusion pathway assessment. Operation of the Site as a heifer raising farm constitutes a known source for potential vapor intrusion. No known sources for potential vapor intrusion were identified for any adjacent or nearby properties.

The former onsite operations have been identified elsewhere in this report as *recognized environmental conditions* or *other environmental features*.

6. Summary of Key Previous Investigations

The following sections provide a summary of previous environmental investigations at the Site, particularly in regard to the former gasoline and diesel USTs at the Site.

Westra Dairy Farm, located at 870 Sanderson Avenue, was identified in the GeoTracker database as having a closed Leaking Underground Storage Tank (LUST) file. According to records provided by the SA-RWQCB, the former on-Site dairy farm (or heifer ranch) had two 1,000-gallon gasoline USTs and one 10,000-gallon diesel UST. The locations of the former USTs as provided by these documents are included in Figure 2.

6.1 Site Investigation (ATC, 2000)

Under direction of the County of Riverside, two 1,000-gallon USTs and one 10,000-gallon USTs were removed from the Site in December 1999. The tank area was over-excavated and approximately 120 tons of hydrocarbon-impacted soil were removed and transported for off-Site disposal. ATC was retained to delineate the vertical and lateral extent of impacts to the soil.

In October 2000, three borings (S-1, S-2, and S-3) were drilled in the area of the former USTs to depths of 60 and 70 feet bgs. Groundwater was not encountered during this investigation. Soil samples were collected at 5-foot intervals starting at 15 feet bgs to the total depth of each boring. Soil samples were analyzed for total petroleum hydrocarbons (TPH) as gasoline (TPH-g) and diesel (TPH-d) and aromatic hydrocarbons. Selected samples collected at 15 feet from S-1 and S-3 were also analyzed for fuel oxygenates, alcohols, and semi-volatiles at the request of the SA-RWQCB.

Based on the analytical results of the soil sampling, ATC determined that the extent of the contamination was “very limited”, and the vertical extent reached below the former tanks to a depth of 35 feet.

6.2 Well Installation and Vapor Extraction Testing (Stratus, 2001)

In accordance with a workplan approved by the SA-RWQCB, Stratus installed one vapor extraction well (VE-1) to assess if any residual petroleum hydrocarbon source remained in the soil that would pose a threat to groundwater resources. VE-1 was installed to a terminal depth of 20 feet bgs and located on the northeastern corner of the former tank excavation. Soil samples were collected at 5-foot intervals and screened using a photoionization detector (PID).

Following the installation of the vapor extraction well in May 2001, a mobile soil vapor extraction (SVE) system was used to extract and treat soil vapors. A vapor extraction test was conducted for 7 hours and reportedly removed an estimated 9.55 pounds of vapor-phase hydrocarbons. Influent soil vapor samples were collected at the startup, mid-point, and end-point of the vapor extraction test and analyzed for volatile fuel hydrocarbons (VFH), benzene, toluene, ethylbenzene, total xylenes (BTEX), and methyl tert-butyl ether (MTBE). Laboratory results of the end-point vapor sample identified VFH at 2,300 parts per million volume (ppmv), benzene at 17 ppmv, toluene at 57 ppmv, total xylenes at 24 ppmv, and MTBE at 270 ppmv. Soil samples do not appear to have been collected following the vapor extraction test. It is unknown if the SVE system operated outside of the 7-hour vapor extraction test as part of remediation for the impacted soils.

A “No Further Action” letter was issued by the SA-RWQCB to the Westra Family Trust on December 26, 2001. The closure letter recommended that correction action should be reviewed if land use changes. According to the “No Further Action” letter, data from this investigation indicates that the residual petroleum hydrocarbons in soil are limited to an area with a 15-foot radius between 15 and 20 feet bgs and did not

indicate a significant presence or source of petroleum hydrocarbons in the soil. At the request of the SA-RWQCB, the vapor extraction well at the Site (identified as a "study well") was properly sealed and abandoned by April 15, 2002.

Although a closure document was issued by the SA-RWQCB in 2001, the remaining petroleum hydrocarbon-impacted soil in the former LUST area is considered a hREC.

6.3 Draft Environmental Impact Report (Dudek, 2009)

Dudek prepared an Environmental Impact Report (EIR) for the City of San Jacinto for the proposed Villages of San Jacinto redevelopment project (the Site). The Villages of San Jacinto project consisted of mixed-use redevelopment of the Site including parks, residences, and a high school. Included in the EIR is a reference to a previous Phase I ESA prepared by Gradient Engineers, dated October 10, 2002. A copy of this report was not included in the appendices provided to Roux. Roux has requested a copy of the 2002 Phase I ESA from the City of San Jacinto; however, records have not been provided as of this writing. The following on-Site environmental hazards were identified in the EIR, particularly regarding the former agricultural operations and petroleum storage.

- **Former Heifer Farm**. A southeastern portion of the Site, totaling approximately 20 acres in size, was formerly developed as a heifer raising farm from at least 1978 through 2002. The former heifer farm operations represented a REC due to the possible presence of methane from manure. According to the EIR, the Riverside County's Methane Investigation Protocol would be followed in order to ensure that methane hazards do not exist on the 20-acre portion of the Site formerly used for heifer raising. Methane gas sampling and associated mitigation activities were reportedly planned after grading, in accordance with RCDEH protocols.

- **Petroleum-Stained Soil.** During the 2002 Phase I ESA, petroleum-stained soil was observed beneath a diesel aboveground storage tank (AST) located northwest of the reservoir (pond), near the irrigation groundwater well located southwest of the reservoir, and on the floor of the equipment shed, beneath three oil-containing 55-gallon drums. Based on the storage of hazardous substances and petroleum products in uncovered ground areas and evidence of a release, the former chemical storage identified above represented a REC. In order to evaluate and possibly mitigate environmental hazards associated with petroleum releases, the EIR recommend sampling and proper disposal of stained soils.

- **Septic Systems.** According to the EIR, the Site was equipped with two septic systems that historical sources suggest may have been in operation for many decades. The EIR stated the septic systems would be removed along with any residue material in accordance with RCDEH protocols. Based on the likely use of these systems for domestic waste only, the existing septic systems represent an OEF.

- **Debris.** Debris, including old equipment, water heaters, tires, and trash were observed in several piles throughout the site both in the 2002 Phase I ESA and during Site reconnaissance associated with the EIR. Several mounds of soil also were observed across the Site. According to the EIR, the soil piles were generated from on-Site activities and were piled for storage and eventual removal. The EIR recommended a qualified environmental professional be present on-Site during removal of debris piles to assess debris and stockpiled soils and direct disposal accordingly. All debris would be disposed of in accordance with state and local laws. Based on observations made during the Site reconnaissance, on-Site debris represent an OEF.

7. Database Records Review

7.1 Standard Environmental Record Sources

According to ASTM Standard E1527-13, the purpose of reviewing regulatory records is to obtain and review records that will help identify *recognized environmental conditions* in connection with the Site. In addition, some records to be reviewed pertain not only to the Site, but also to properties within an additional "approximate minimum search distance" in order to help assess the likelihood of problems from migrating hazardous substances or petroleum products. The basis of the "approximate minimum search distance" is the Site boundary.

Roux retained EDR of Shelton, Connecticut to provide an ASTM Radius Map Report (EDR Report) for this Site. This report is a computerized search of select state and federal environmental databases that identify various properties with a record of environmental activity. Roux reviewed the report and summarized the relevant findings in the following sections. A copy of the compiled EDR Report has been included as Appendix F. The EDR report includes a detailed description of each of the databases searched, providing a summary of the type of information provided by each. A summary of Roux' review of the EDR Report listings is provided in Table 1.

The following section describes the findings of the database search. Roux used professional judgement in determining which EDR-listed sites to include in the narrative of this report. Facilities adjoining the Site were included due to their proximity to the Site and the potential for surface water discharges (e.g., storm water runoff, surface water effluent discharges) to enter the Site or through the migration of groundwater. Sites with listings indicative of a release (e.g., SHWS, LUST, RELEASE) are likewise discussed below. Nonadjacent facilities with database listings not necessarily indicative of a release (hazardous waste generator, FINDS, ECHO, NPDES, HAZNET, AST, or UST) will not be discussed unless considered potentially relevant in context of the Phase I ESA.

7.1.1 Site (Target Property)

Address	Owner/Operator	Database(s)
870 Sanderson Avenue	None identified	CHMIRS
	Western Family Trust	HAZNET, HWTS
	Westra Dairy Farm	RGA LUST, LUST, Cortese, CERS, FINDS
	Quality Turf	FINDS
	Proposed High School at the Villages of San Jacinto	ENVIROSTOR, SCH

According to the CHMIRS listing, Riverside County Fire Department was called to a burning operation at a dairy on January 28, 1999. Ten 55-gallon drums of waste motor oil were identified to be leaking and overturned. There was reportedly evidence that some oil had been dumped into a refuse pit and burned. No additional pertinent information such as the location of the drums or cleanup activities were provided. Roux

requested records from Riverside County Fire Department on July 29, 2021. No response has been received as of this report date.

In 1999, Western Family Trust generated 4.17 tons of off-specification, aged or surplus inorganics at the Site. This listing may be associated with removal of hazardous waste drums such as the 10 drums identified in the CHMIRS. Environmental concerns associated with former aboveground chemical storage at the Site are discussed in Section 6.0.

Westra Dairy Farm was identified as a closed Leaking Underground Storage Tank (LUST) facility. According to the listings, a release of gasoline to soil was remediated under oversight of the Santa Ana Regional Water Quality Control Board. The closed LUST case is further discussed above in Section 6.0.

According to client-provided information, a portion of the Site was formerly proposed to be redeveloped with a school campus. The proposed school facility, located at Ramona Boulevard and Cawston Avenue, was identified as a school investigation EnviroStor listing. The closed EnviroStor case is further discussed above in Section 8.1.

7.1.2 Adjoining and Nearby Properties

Discussions of adjoining and nearby properties of potential environmental concern as noted in Table 1 are provided below.

- **EMWD San Jacinto Valley RWRF / Hemet San Jacinto Reg Water (770 North Sanderson Avenue).** The south adjacent site, identified as a sewage treatment facility, was identified in the AST, RCRA-LQG, CERS HAZ WASTE, CERS TANKS, CHMIRS, NPDES, CIWQS, and CERS database. According to the AST listing, this facility is equipped with ASTs totaling 3,720 gallons in capacity. The quantity and contents of the tanks were not provided. The RCRA-LQG listing indicates ignitable waste, corrosive waste, and lead have been generated by the facility. This adjacent site has reportedly been issued a construction stormwater permit by the Eastern Municipal Water District. Absent any additional information, this adjacent site is not expected to represent a significant environmental concern to the Site based on the lack of a documented release.

7.1.3 Orphan Sites

The EDR Report includes a section addressing “Orphan Sites.” Orphan sites are sites, which, due to incomplete geographic location data, incomplete address information or incorrect address information, cannot be plotted correctly. The database report identified one unmapped facility.

- **Hemet/San Jacinto WWRD (770 Sanderson).** The south adjacent site was identified in the CIWQS database. This listing pertains to an inactive industrial stormwater permit issued to the facility by the Eastern Municipal Water District. Based on the lack of a documented release associated with this facility, this listing is not expected to represent a significant environmental concern.

8. Findings

Roux has performed this Phase I ESA in general compliance with the scope and limitations of ASTM Standard Practice E1527-13. Roux separated the findings of this assessment into the following four categories: *recognized environmental conditions*, *controlled recognized environmental conditions*, *historical recognized environmental conditions* and *other environmental features*.

8.1 Data Gaps

During conduct of this ESA, the following data gaps, as defined in ASTM Standard E1527-13 were identified:

- The timing of the report did not allow for all contacted agencies to respond to the records requests issued, including a request pending with the City of San Jacinto City Clerk. This data gap is not considered significant due to sufficient information available from previous environmental reports, the EDR report, and city, county, and state websites.
- Previous Site owners/operators were not available for an interview. On August 26, 2021, Roux attempted to reach an owner of the Site, Mr. Cal Westra, via telephone. Roux was informed that the phone number for Mr. Westra had been reassigned. This data gap is not considered significant due to sufficient information regarding Site history available from EDR historical documents and FOIA requests.
- Roux observed the Site from accessible road throughout the Site. Due to the size of the property and the vegetation present on site, isolated areas of the site may have not been accessible for direct observation during the Site reconnaissance.
- A portion of the Site is listed by the California DTSC as the "Proposed High School at the Villages of San Jacinto" (Global ID T60000906) at the intersection of Ramona Boulevard and Cawston Avenue. Three pages of a PEA report including the introduction and part of the executive summary are available on EnviroStor appended to a response to comments matrix; however, the full PEA document is not available online. Roux contacted the DTSC Cypress office for copies of the PEA reports. Ms. Gloria Conti and Ms. Jone Barrio of the DTSC Cypress office informed Roux that no other pertinent records for the proposed high school are on file with the DTSC and have likely been purged. Roux' inability to obtain a copy of the previous PEA report represents a data gap. Based the limited information available online for the PEA and NFA letter issued by the DTSC, this limitation is not expected to alter the findings of this assessment.

8.2 Recognized Environmental Conditions

Based on the information obtained through the performance of this ESA, Roux identified the following RECs in connection with the current and historical operations at the Site or adjacent properties. To the extent possible, the locations of the RECs are shown in Figure 2. To avoid confusion, all RECs, cRECs, and hRECs, and OEFs are numbered sequentially.

REC 1 – Former Heifer Farm. A southeastern portion of the Site, totaling approximately 20 acres in size, was formerly developed as a heifer raising farm from at least 1978 through 2002. The former heifer farm operations represented a REC due to the possible presence of methane from manure.

REC 2 - Petroleum-Stained Soil. During a reconnaissance of the Site conducted in 2002, petroleum-stained soil was observed beneath a diesel AST located northwest of the reservoir (pond), near the irrigation groundwater well located southwest of the reservoir, and on the floor of the equipment shed, beneath three oil-containing 55-gallon drums. Based on the storage of hazardous substances and

petroleum products in uncovered ground areas and evidence of a release, the former chemical storage identified above represented a REC.

REC 3 - Pond. The Site is equipped with a pond located on the southwestern corner. According to aerial photographs, the pond was added between 1978 and 1985 and was likely used as part of the heifer ranch operations. According to a 2009 EIR, the reservoir contained reclaimed water from the neighboring San Jacinto Valley Regional Water Reclamation Facility related to irrigation for sod farming activities on-Site. It is unknown whether the pond also historically received wastewater from the on-Site ranch operations, was used for agricultural irrigation, or stored water treated with larvicide/repellant for mosquito control. The pond appeared unlined, allowing waters to infiltrate the ground and recharge the aquifer. Based on the historical agricultural use of the Site, the on-Site pond represents a REC.

REC 4 - Former Agricultural Applied Pesticide Area. Based on a review of historical sources, a portion of the Site was developed for agricultural use (row crops) as early as 1949 with increased agricultural development noted from at least 1978 to 2016. No indications of former row crops were observed on the Site. According to the EIR, a portion of the Site was developed as a sod farm from 1997 through at least 2002. Any residual pesticide, herbicide, or fertilizer residue in Site soils associated with sod farming was not identified as an environmental concern based on the removal of shallow soils during sod harvest. Agricultural production prior to 1997 at the Site is not currently known. However, it is likely that agricultural chemicals, such as pesticides, herbicides, and fertilizers, were used on-Site historically, and the potential for impacts from agricultural chemicals to on-Site soils is considered a REC.

8.3 Controlled Recognized Environmental Conditions

Roux did not identify known or suspected cRECs in connection with the current and historical operations at the Site

8.4 Historical Recognized Environmental Conditions

Roux identified the following hRECs in connection with the current and historical operations at the Site or adjacent properties. To the extent possible, the locations of the hRECs are shown in Figure 2.

hREC 5 – Historical Underground Storage Tanks. Westra Dairy Farm, formerly located on-Site at 870 Sanderson Avenue, was identified as having a closed LUST file. According to closure documents, the former on-Site dairy farm (or heifer ranch) had two 1,000-gallon gasoline USTs and one 10,000-gallon gasoline UST located south of a former workshop building in the southern portion of the Site. All three USTs were removed from the Site in December 1999 under direction of the County of Riverside. The tank area was over-excavated and approximately 120 tons of contaminated soil were removed and transported for off-Site disposal. In October 2000, a soil investigation identified TPH and VOC impacts below the former tanks to a depth of 35 feet bgs. In May 2001, a vapor extraction well was subsequently in the vicinity of the former tanks and a mobile soil vapor extraction system was used to extract and treat soil vapor. Soil samples do not appear to have been collected following the vapor extraction test. It is unknown if the SVE system operated outside of the 7-hour vapor extraction test as part of remediation for the impacted soils. A “No Further Action” letter was issued by the SA-RWQCB to the Westra Family Trust on December 26, 2001. The closure letter recommended that correction action should be reviewed if land use changes. According to the “No Further Action” letter, data from this investigation indicates that the residual petroleum hydrocarbons in soil are limited to an area with a 15-foot radius between 15

and 20 feet bgs and did not indicate a significant presence or source of petroleum hydrocarbons in the soil. Although a closure document was issued by the SA-RWQCB in 2001, the remaining petroleum hydrocarbon-impacted soil in the former LUST area is considered a hREC.

8.5 Other Environmental Features

OEFs are environmental conditions that do not meet the definition of a REC, cREC, or hREC, but which may warrant mention in a comprehensive Phase I ESA. Based on the subject Phase I ESA, Roux identified the following OEFs at or in the vicinity of the Site. To the extent possible, the locations of the OEFs are shown in Figure 2.

OEF 6 - Septic Systems. According to the EIR, the Site was equipped with two septic systems that historical sources suggest may have been in operation for many decades. The EIR stated the septic systems would be removed along with any residue material in accordance with Riverside County Department of Environmental Health (RCDEH) protocols. Based on the likely use of these systems for domestic waste only, the existing septic systems represent an OEF.

OEF 7 - Debris. Debris, including old equipment, water heaters, tires, and trash were observed in several piles throughout the site both in the 2002 Phase I ESA and during Site reconnaissance associated with the EIR. Several mounds of soil also were observed across the Site. According to the EIR, the soil piles were generated from on-Site activities and were piled for storage and eventual removal. The EIR recommended a qualified environmental professional be present on-Site during removal of debris piles to assess debris and stockpiled soils and direct disposal accordingly. Based on observations made during the Site reconnaissance, on-Site debris represent an OEF.

OEF 8 - Abandoned Drums. Two abandoned 55-gallon drums were observed during Roux' Site reconnaissance on August 3, 2021. The drums were observed on a concrete pad in the southeastern portion of the Site in the vicinity of the former heifer ranch area and appeared to contain unknown waste products. Minor to moderate staining was observed in the vicinity of these features. The staining was located on a paved area. It appears that the staining is surficial in nature and thus is not expected to represent a significant environmental concern.

10. Signature of Environmental Professional

Roux performed this assessment in accordance with the generally accepted practices for environmental assessments at the time of implementation. Roux made a reasonable effort to ensure that the information presented in this report is materially complete and accurate.

Roux completed a Phase I ESA in general compliance with the scope and limitations of ASTM Practice E1527-13 of the vacant property located at west of North Sanderson Avenue, San Jacinto, Riverside County, California.

"We declare that, to the best of our professional knowledge and belief, we meet the definition of Environmental professional as defined in §312.10 of 40 CFR 312" and,

"We have the specific qualifications based on education, training, and experience to assess a property of the nature, history, and setting of the Subject property. We have developed and performed the all appropriate inquiries in conformance with the standards and practices set forth in 40 CFR Part 312."

Roux performed this Phase I ESA by, or under direct supervision of, the undersigned environmental professionals.

Respectfully Submitted,

ROUX ASSOCIATES, INC.

Re: Phase II Subsurface Investigation Letter Report
Proposed Industrial Building Complex, North Sanderson Avenue, San Jacinto, Riverside County, California

Dear Mr. Perales:

Roux Associates, Inc. (Roux) has prepared this Phase II Subsurface Investigation Letter Report (Report) for Shea Properties (CLIENT) to summarize the findings of the subsurface investigations conducted at the approximately 470-acre vacant property located west of North Sanderson Avenue, east of Odel Avenue and south of Ramona Boulevard in the City of San Jacinto, California (Site; Figure 1). The scopes of work, as detailed in Roux's proposals dated August 19, 2021 and October 1, 2021, were developed to address recognized environmental conditions (RECs), identified by Roux in the Phase I Environmental Site Assessment (Phase I ESA), dated October 25, 2021.

The Phase II Investigation focused on addressing the following RECs:

- Potential pesticide impacts to shallow soils from former agricultural (row crop) uses;
- Potential VOC, metals, pesticides, total petroleum hydrocarbon (TPH), and/or methane impacts from former on-Site heifer raising farm uses, including multiple livestock corrals and an unlined pond; and
- Potential petroleum impacts from former on-Site aboveground storage tanks (ASTs);

The sections that follow provide additional details of the investigation activities completed.

METHODS OF INVESTIGATION

Pre-Field Activities

Prior to the start of field activities, Roux prepared a Site-specific Health and Safety Plan (HASP) to ensure worker safety. In addition to containing information regarding Roux's standard safety practices, the HASP contained information about potential hazards related to Site activities and provided the locations and contact information of nearby emergency services. Field workers acknowledged their familiarity with all safety procedures and indicated their intent to follow the HASP by signing the HASP after the tailgate safety meeting, which took place at the beginning of each field day.

At least 48 hours prior to fieldwork, the areas of the Site targeted for the investigation were marked in white paint and Underground Service Alert (USA) was notified of the intended intrusive work. Additionally, to assess the locations of buried utilities (i.e., natural gas, electric, water, sewer, telephone, fiber optic, etc.) or obstructions, a private geophysical services and utility locating firm, Spectrum Geophysics of Chatsworth, California, was contracted to perform a geophysical survey to clear the proposed boring locations of potential subsurface obstructions prior to boring advancement.

Soil Sampling – Agricultural Uses

On September 1 and 2, 2021, a total of 184 soil samples were collected from 46 quadrants (SS-1 through SS-46) across the Site at depths of 0.5 feet below ground surface (bgs) as shown in Figure 2. Soil sampling locations were evenly distributed in a grid pattern across each quadrant.

Four soil samples were collected with a trowel and/or a hand auger from each quadrant, composited in the field, and placed into laboratory-provided glass jars. A total of 184 soil samples were composited into 46 composite samples (SS-COMP-1 through SS-COMP-46).

After sample collection, all soil samples were labeled, placed on ice, and transported under chain-of-custody to Enthalpy Analytical (Enthalpy) of Garden Grove, California, a California-certified laboratory. Soil samples were analyzed in accordance with the sampling and analysis plan as shown in Table 1.

Soil Sampling – USTs, Livestock, and Unlined Pond

On September 7, 2021, under the direction of Roux, Strongarm Environmental Field Services, Inc. (Strongarm) of Fullerton, California advanced 10 soil borings (SV-1 through SV-10, Figure 2). The sampling locations for this investigation targeted the former USTs. Borings SV-1 and SV-2 were advanced to a depth of 5 feet below ground surface (bgs) using a hand auger to clear for utilities and subsequently drilled to the terminal depth of 20 feet bgs using a direct push drilling rig. Borings SV-3 through SV-10 were advanced to a terminal depth of 5.5 feet bgs using a hand auger.

Based on the laboratory results for samples collected on September 7, 2021, additional soil samples were collected on October 8, 2021. Under the direction of Roux, Strongarm advanced seven additional borings at the Site. Two borings, SV-1A and SV-3A, were placed near the original SV-1 and SV-3 locations, respectively. Five additional borings (SV-11 through SV-15, Figure 3) were placed in the proximity of the former residential/agricultural structures on-Site. All borings were pre-cleared to a depth of 5 feet bgs using a hand auger to check for utilities and subsequently drilled to a terminal depth of 25 feet bgs using a direct push drilling rig.

During boring advancement, soil samples were collected from borings SV-1 and SV-2 at depths of 5, 10, 15, and 20 feet bgs; from borings SV-3 and SV-4 at 5 feet bgs; and from borings SV-5 at 0.5 and 5 feet bgs. The soil samples collected at 0.5 feet bgs from borings SV-5 as well as all soil samples collected at 5 feet bgs from borings SV-1 through SV-5 were collected directly from the hand auger bucket. The soil samples collected at depths of 10, 15, and 20 feet bgs from borings SV-1 and SV-2 were collected from acetate sleeves.

After sample collection, all soil samples were labeled, placed on ice, and transported under chain-of-custody to Enthalpy of Garden Grove, California, a California-certified laboratory. Soil samples were analyzed in accordance with the sampling and analysis plan as shown in Table 1.

Soil Vapor Probe Installation

On September 7, 2021, following advancement of borings SV-1 through SV-10, temporary soil vapor probes were installed. Dual-nested soil vapor probes were installed at depths of 5 feet bgs and 15 feet bgs at locations SV-1 and SV-2. Soil vapor probes were installed at 5 feet bgs at SV-3 through SV-10. Soil vapor sampling locations are shown in Figures 3 and 4.

On October 8, 2021, following advancement of borings SV-1A, SV-3A, and SV-11 through SV-15, temporary soil vapor probes were installed. One soil vapor probe was installed at a depth of 25 feet bgs at location SV-1A, one dual-nested soil vapor probe was installed at 15 and 25 feet bgs at location SV-3A, and five triple-nested soil vapor probes at depths of 5, 15, and 25 feet bgs were installed at locations SV-11 through SV-15. Soil vapor sampling locations are shown in Figures 3 and 4.

The soil vapor probes were constructed in general accordance with the California Environmental Protection Agency, Department of Toxic Substances Control (DTSC), Los Angeles Regional Water Quality Control Board (LARWQCB), and San Francisco Regional Water Quality Control Board Advisory, Active Soil Gas Investigations (Soil Gas Advisory), dated July 2015. After the installation of each soil vapor probe, a minimum 48-hour equilibrium period was observed prior to sampling the five-foot probes and a minimum two-hour equilibrium period was observed prior to sampling 15-foot and 25-foot probes, per the Soil Gas Advisory.

Soil Vapor Sampling

On September 10, 2021, Roux collected samples from the temporary soil vapor probes installed at SV-1 through SV-10. On October 11, 2021, under the direction of Roux, Optimal Technology (Optimal) of Thousand Oaks, CA, collected samples from the temporary soil vapor probes installed at SV-1A, SV-3A, and SV-11 through SV-15. Prior to purging and sampling, a shut-in test was performed at each probe to confirm that the above-ground lines and valves were properly sealed. Upon successful completion of the shut-in test, three purge volumes of stagnant air were subsequently extracted from the soil vapor probe system at a flow rate of 200 milliliters per minute (mL/min). During purging and sampling, a leak check compound, 1,1-difluoroethane (1,1-DFA) or Isobutane, was applied adjacent to the sample train connections as a tracer gas to detect potential leaks in the sampling system.

After purging soil vapor probes SV-1 through SV-10, Roux collected soil vapor samples using 1-liter summa canisters equipped with 200 mL/min flow controllers. Following sample collection, soil vapor samples were transported under proper chain of custody to Enthalpy.

After purging soil vapor probes SV-1A, SV-3A, and SV-11 through SV-15, Optimal collected soil vapor samples in laboratory-prepared glass syringes; and immediately analyzed them on-Site using a mobile laboratory.

Soil vapor samples collected from SV-1 through SV-4, SV-1A, SV-3A, and SV-11 through SV-15 were analyzed for VOCs by USEPA Method TO-15 or USEPA Method 8260B. Soil vapor samples collected from SV-5 through SV-10 were analyzed for VOCs by USEPA Method TO-15 and methane by ASTM Method D-1946.

RESULTS

Analytical results for soil samples are summarized in Tables 2 through 5, and soil vapor results are presented in Tables 6 and 7. The complete analytical laboratory reports are included in Attachment A.

Soil Results

The sections that follow provide a summary of the soil analytical results. Soil sampling locations are shown in Figures 2 and 3.

OCPs

A summary of analytical results for OCPs in soil is presented in Table 2.

In general, individual OCP constituents were reported above laboratory method reporting limits (MRLs) in several borings including:

- dichlorodiphenyldichloroethane (4,4'-DDD);
- dichlorodiphenyldichloroethylene (4,4'-DDE);
- dichlorodiphenyltrichloroethane (4,4'-DDT); and

- eldrin aldehyde.

Detected concentrations were compared to the applicable May 2021 USEPA Regional Screening Level (RSL) for industrial soil and the June 2020 DTSC Human and Ecological Risk Office (HERO) Human Health Risk Assessment (HHRA) Note 3 Screening Level for industrial/commercial soil.

Conclusion: No OCPs were detected above the commercial/industrial screening levels established by USEPA RSLs or DTSC HERO HHRA Note 3 SLs.

Metals

A summary of analytical results for metals in soil is presented in Table 3. A total of 11 metals were detected above laboratory detection limits in at least one of the soil samples analyzed. Detected concentrations were compared to the applicable May 2021 USEPA RSL for industrial soil and the June 2020 DTSC HERO HHRA Note 3 Screening Level for industrial/commercial soil.

Arsenic was detected at concentrations exceeding the regulatory screening levels, ranging from 1.0 to 9.3 milligrams per kilogram (mg/kg), which exceeds the DTSC Note 3 SL (0.36 mg/kg). However, arsenic concentrations were below the upper range of the *Southern California Regional Background Arsenic Concentration in Soil* (Determination of a Southern California Regional Background Arsenic Concentration in Soil, G., Bosan, W., and Outiz, D., DTSC) of 12 mg/kg.

Conclusion: No metals were above background concentrations or the commercial/industrial screening levels established by USEPA RSLs or DTSC HERO HHRA Note 3 SLs.

TPH

A summary of the analytical results for TPH in soil is presented in Table 4.

Conclusion: TPH was not detected above laboratory reporting limits in carbon ranges C6-C44 in any of the samples analyzed.

VOCs

A summary of the analytical results for VOCs in soil is presented in Table 5. Two VOCs, methylene chloride and tert-butyl alcohol (TBA), were detected above laboratory reporting limits in at least one soil sample.

Conclusion: VOCs were not detected above either the applicable USEPA RSL for industrial soil or the DTSC SL for commercial/industrial soil.

Soil Vapor Results

The sections that follow provide a summary of the soil vapor analytical results. A summary of the soil vapor analytical results is presented in Tables 6 and 7. Soil sampling locations are shown in Figures 2 and 3.

VOCs

A summary of the analytical results for VOCs in soil vapor is presented in Table 6.

A total of 17 VOCs were detected above laboratory reporting limits in at least one soil vapor sample. Detected concentrations were compared to the applicable USEPA RSL for commercial/industrial soil vapor and the DTSC SL for commercial/industrial soil vapor when an attenuation factor of 0.03 was applied.

- Trichloroethene (TCE) was detected in soil vapor at concentrations exceeding screening levels. TCE was detected above the applicable USEPA RSL (100 micrograms per cubic meter [µg/m^3]) in two samples (SV-1-15 and SV-3-5) at concentrations of 110 µg/m^3 and 210 µg/m^3, respectively.

    - Borings SV-1 and SV-3 were located in the area of former residential and agricultural structures including a maintenance building.

    - All detections of TCE were below the applicable DTSC SL (267 µg/m^3).

    - Additional soil vapor sampling, focused in the area of the former residential/agricultural structures, did not yield detectable concentrations of TCE above laboratory reporting limits.

Conclusion: TCE was detected at concentrations that exceeded applicable conservative USEPA RSL at two locations. However, no sources were identified on-Site and the generally low TCE concentrations do not suggest that any mitigation or remediation will be required. All other VOCs were below the DTSC's Commercial/Industrial Soil Vapor SL or USEPA's Industrial Soil Vapor RSL.

Methane

A summary of the analytical results for methane in soil vapor is presented in Table 7.

Methane was detected above laboratory method reporting limits in six soil vapor samples (SV-5-5 through SV-10-5) at concentrations ranging from 2.3 parts per million by volume (ppmv) to 3.7 ppmv. Detections of methane did not exceed the cautionary value of 1,000 ppmv or response value of 5,000 ppmv established by the DTSC Advisory on Methane Assessment and Common Remedies at School Sites.

Conclusion: Methane concentrations detected at the Site do not present a potential concern for the Site.

RECOMMENDATIONS

Based on the results of this Phase II Subsurface Investigation, Roux has addressed the RECs identified in the Phase I ESA and does not have any additional recommendations at this time.

CLOSING

Should you have any questions or require any further information regarding the contents of this Report, please do not hesitate to contact Mauricio Escobar by telephone at 310-879-4920 or by email at mescobar@rouxinc.com.

Sincerely,

ROUX ASSOCIATES, INC.

Mauricio Escobar, P.G.
Principal Geologist

[a] Upper-bound background concentrations from Chernoff, G., Bosan, W., and Outiz, D., DTSC. Determination of a Southern California Regional Background Arsenic Concentration in Soil.

USEPA = United States Environmental Protection Agency

USEPA RSL = USEPA Regional Screening Level for industrial soil, dated May 2021

DTSC SL = Department of Toxic Substances Control Human and Ecological Risk Office (HERO) Human Health Risk Assessment (HHRA) Note 3 Screening Level for industrial/commercial soil, dated June 2020

* SL is for "Lead and Compounds"

mg/kg = milligrams per kilogram

bgs = below ground surface

<X = not detected above laboratory reporting limits

Bold indicates value exceeds laboratory reporting limit

Italics indicates duplicate sample

Yellow = Concentration exceeds DTSC SL but does not exceed USEPA RSL

Orange = Concentration exceeds USEPA RSL

NS = no screening criteria available

Notes:

[1] Soil Gas Screening Levels (SGSLs) were calculated by applying an attenuation factor of 0.03 to the DTSC SLs or USEPA RSLs, per the DTSC Draft Supplemental Guidance, dated February 2020
USEPA = United States Environmental Protection Agency
USEPA RSL = USEPA Regional Screening Level for industrial air, dated May 2021
DTSC SL = Department of Toxic Substances Control Human and Ecological Risk Office (HERO) Human Health Risk Assessment (HHRA) Note 3 Screening Level for industrial/commercial air, dated June 2020; and DTSC HERO HHRA Note 5 Trichloroethene Indoor Air Response Action Levels for Commercial/Industrial (8-hour workday), dated August 23, 2014
µg/m^3 = micrograms per cubic meter
Only compounds detected in soil vapor above laboratory reporting limits in at least one sample are shown on this table
<X = not detected above laboratory reporting limits
Bold indicates value exceeds laboratory reporting limit
Italics indicates duplicate sample
Orange = Concentration exceeds USEPA RSL
NS = no screening criteria available

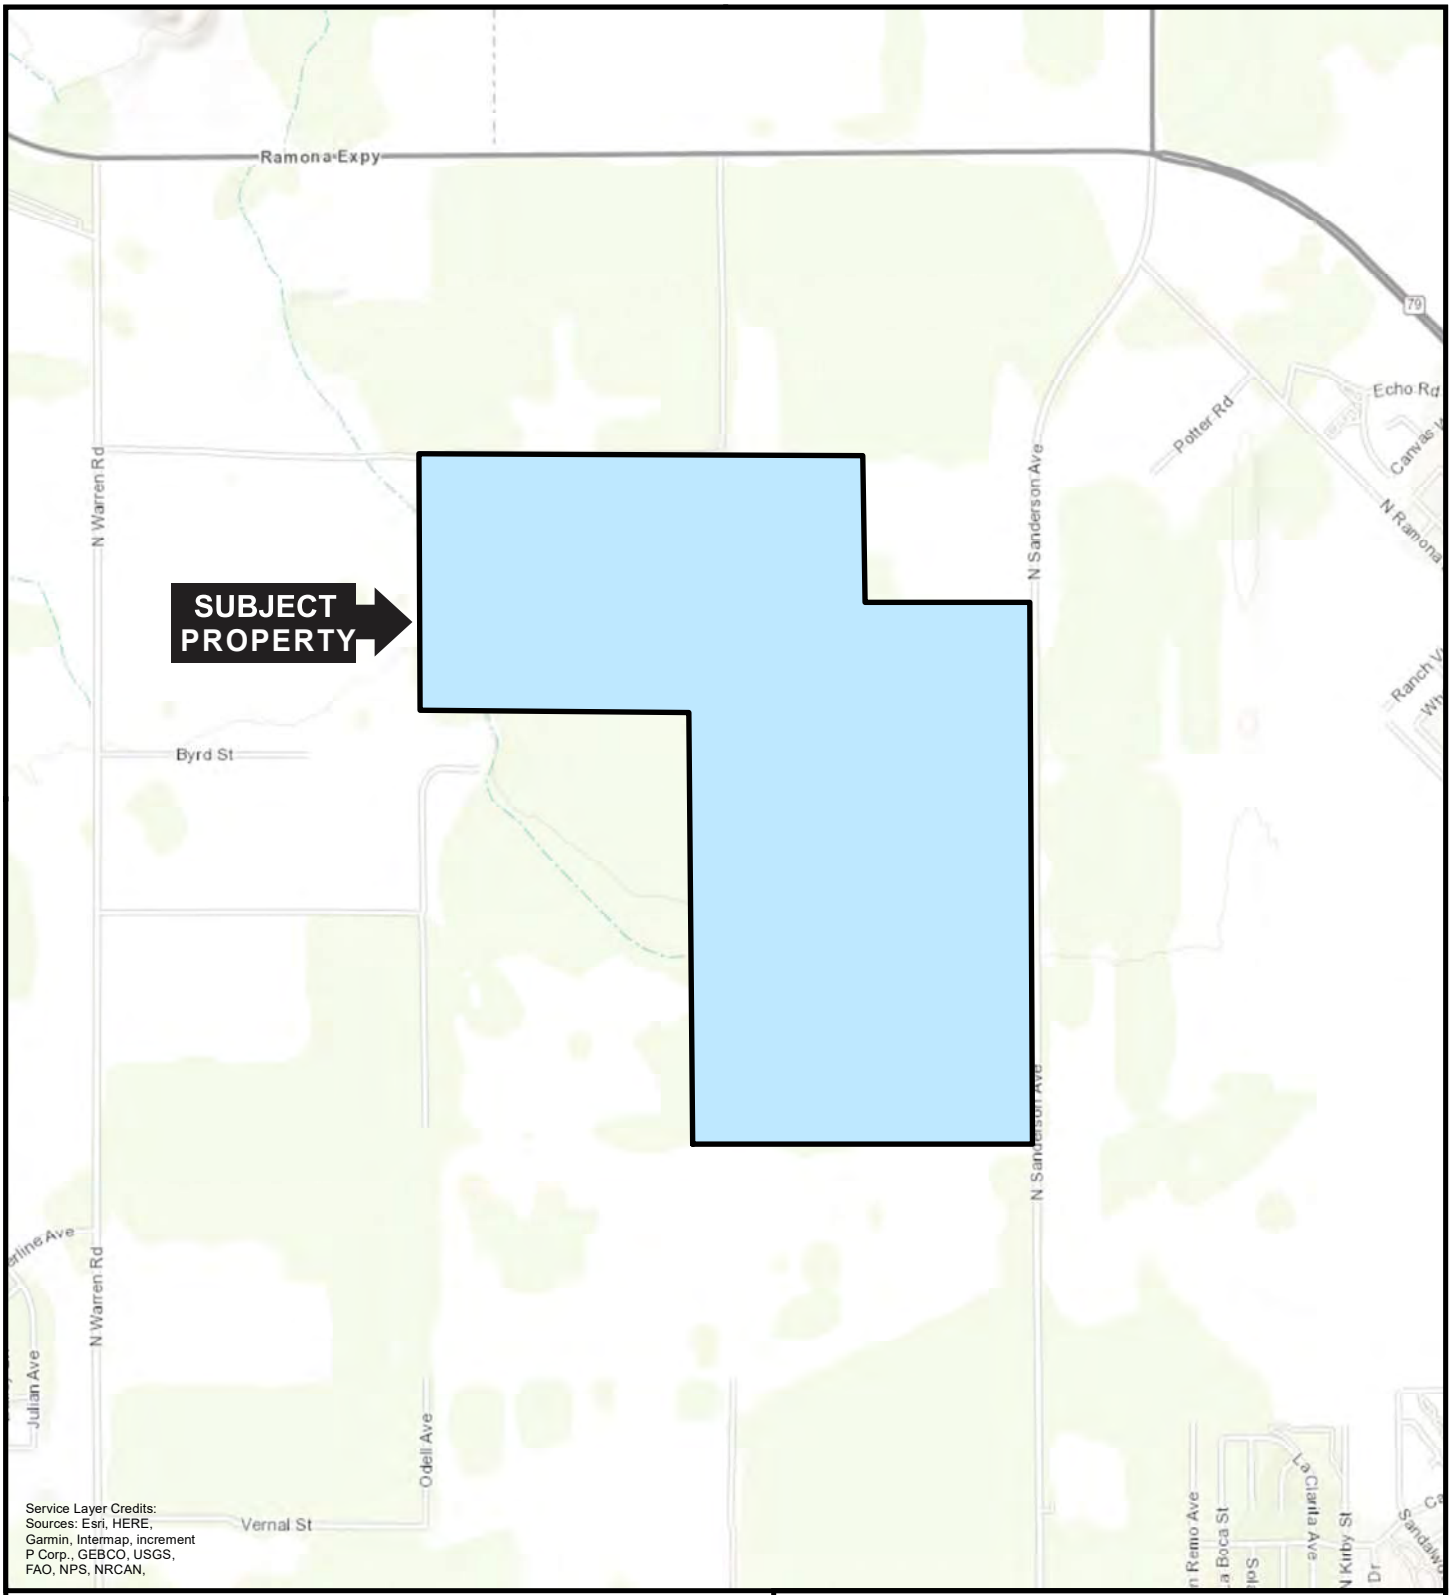

Table 7. Methane in Soil Vapor
870 North Sanderson Avenue
San Jacinto, CA

Sample ID	Sample Depth (feet bgs)	Sample Date	Methane
		Analytical Method	ASTM D-1946
		DTSC Cautionary Value for Methane	1,000
		DTSC Response Value for Methane	5,000
		Units	ppmv
SV-5-5	5	9/10/2021	**3.7**
SV-6-5	5	9/10/2021	**2.7**
SV-7-5	5	9/10/2021	**2.6**
SV-8-5	5	9/10/2021	**2.8**
SV-9-5	5	9/10/2021	**2.3**
SV-10-5	5	9/10/2021	**2.4**

Notes:
ASTM = American Society for Testing Materials
ppmv = parts per million by volume
Bold indicates analyte detected above method reporting limits
DTSC Cautionary and Response Values = DTSC Advisory on Methane Assessment and Common Remedies at School Sites, dated June 16, 2005.

Case Narrative

Roux Associates, Inc. 5150 E. Pacific Coast Hwy. Suite 450 Long Beach, CA 90804 Rocio Quinones	Lab Job Number:	450050
	Location:	Shea San Jacinto - 870 N. Sanderson Ave., San Jacinto, CA
	Date Received:	09/02/21

This data package contains sample and QC results for fifty one soil samples, requested for the above referenced project on 09/02/21. The samples were received cold and intact.

Pesticides (EPA 8081A):

Low recoveries were observed for endrin aldehyde and endrin ketone in the MS/MSD for batch 273570; the parent sample was not a project sample, and the LCS was within limits. High recoveries were observed for a number of analytes; the LCS was within limits. High RPD was observed for aldrin, endosulfan sulfate, and endrin; these analytes were not detected at or above the RL in the associated sample. High RPD was observed for methoxychlor in the MS/MSD of SS-COMP-1 (lab # 450050-001); this analyte was not detected at or above the RL in the associated samples. High RPD was observed for endrin ketone in the MS/MSD for batch 273369; the parent sample was not a project sample, and this analyte was not detected at or above the RL in the associated samples. Many samples were diluted due to the dark color of the sample extracts. SS-COMP-7 (lab # 450050-008) was diluted due to the color of the sample extract. No other analytical problems were encountered.

Metals (EPA 6010B and EPA 7471A):

High response was observed for antimony in the CCV analyzed 09/09/21 15:28; affected data was qualified with "b". High response was observed for antimony in the CCV analyzed 09/09/21 16:09; affected data was qualified with "b". Low recoveries were observed for antimony in the MS/MSD of SS-COMP-9 (lab # 450050-010); the LCS was within limits, and the associated RPD was within limits. Low recoveries were observed for antimony in the MS/MSD of SS-COMP-25 (lab # 450050-027); the LCS was within limits, and the associated RPD was within limits. High recoveries were observed for silver and barium in the MS of SS-COMP-25 (lab # 450050-027); the LCS was within limits. High RPD was also observed for silver and barium in the MS/MSD of SS-COMP-25 (lab # 450050-027). Low recoveries were observed for antimony in the MS/MSD of SS-COMP-42 (lab # 450050-047); the LCS was within limits, and the associated RPD was within limits. No other analytical problems were encountered.

SAMPLE ACCEPTANCE CHECKLIST

Section 1

Client: Roux Project: San Jacinto

Date Received: 9/2/21 Sampler's Name Present: ☑ Yes ☐ No

Section 2

Sample(s) received in a cooler? ☑ Yes, How many? 2 ☐ No (skip section 2) Sample Temp (°C) (No Cooler): _____

Sample Temp (°C), One from each cooler: #1: 3.8 #2: 5.8 #3: _____ #4: _____

(Acceptance range is < 6°C but not frozen (for Microbiology samples, acceptance range is < 10°C but not frozen). It is acceptable for samples collected the same day as sample receipt to have a higher temperature as long as there is evidence that cooling has begun.)

Shipping Information: _____

Section 3

Was the cooler packed with: ☑ Ice ☐ Ice Packs ☑ Bubble Wrap ☐ Styrofoam ☐ Paper ☐ None ☐ Other _____

Cooler Temp (°C): #1: 2.5 #2: 5.0 #3: _____ #4: _____

Section 4	YES	NO	N/A
Was a COC received?	✔		
Are sample IDs present?	✔		
Are sampling dates & times present?	✔		
Is a relinquished signature present?	✔		
Are the tests required clearly indicated on the COC?	✔		
Are custody seals present?		✔	
If custody seals are present, were they intact?			✔
Are all samples sealed in plastic bags? (Recommended for Microbiology samples)	✔		
Did all samples arrive intact? If no, indicate in Section 4 below.		✔	
Did all bottle labels agree with COC? (ID, dates and times)	✔		
Were the samples collected in the correct containers for the required tests?	✔		
Are the containers labeled with the correct preservatives?			✔
Is there headspace in the VOA vials greater than 5-6 mm in diameter?			✔
Was a sufficient amount of sample submitted for the requested tests?	✔		

Section 5 Explanations/Comments

Sample 8: "SS-Comp-7" Received broken, possible ice water contamination.

Section 6

For discrepancies, how was the Project Manager notified? ☐ Verbal PM Initials: _____ Date/Time _____

☑ Email (email sent to/on): RKC / 9/2/21

Project Manager's response:

Completed By: _____ Date: 9/2/2021

SAMPLE ACCEPTANCE CHECKLIST

Section 1

Client: Roux Associates, Inc. Project: Shea San Jacinto

Date Received: 9/9/21 Sampler's Name Present: ☑ Yes ☐ No

Section 2

Sample(s) received in a cooler? ☑ Yes, How many? 1 ☐ No (skip section 2) Sample Temp (°C) (No Cooler): _____

Sample Temp (°C), One from each cooler: #1: 5.8 #2: _____ #3: _____ #4: _____

(Acceptance range is < 6°C but not frozen (for Microbiology samples, acceptance range is < 10°C but not frozen). It is acceptable for samples collected the same day as sample receipt to have a higher temperature as long as there is evidence that cooling has begun.)

Shipping Information: _____

Section 3

Was the cooler packed with: ☑ Ice ☐ Ice Packs ☐ Bubble Wrap ☐ Styrofoam ☐ Paper ☐ None ☐ Other _____

Cooler Temp (°C): #1: 0.9 #2: _____ #3: _____ #4: _____

Section 4	YES	NO	N/A
Was a COC received?	✔		
Are sample IDs present?	✔		
Are sampling dates & times present?	✔		
Is a relinquished signature present?	✔		
Are the tests required clearly indicated on the COC?	✔		
Are custody seals present?		✔	
If custody seals are present, were they intact?			✔
Are all samples sealed in plastic bags? (Recommended for Microbiology samples)	✔		
Did all samples arrive intact? If no, indicate in Section 4 below.	✔		
Did all bottle labels agree with COC? (ID, dates and times)	✔		
Were the samples collected in the correct containers for the required tests?	✔		
Are the containers labeled with the correct preservatives?	✔		
Is there headspace in the VOA vials greater than 5-6 mm in diameter?			✔
Was a sufficient amount of sample submitted for the requested tests?	✔		

Section 5 Explanations/Comments

Sample " SV-1-10" (Sample 2) received with possible ice water contamination.

Section 6

For discrepancies, how was the Project Manager notified? ☐ Verbal PM Initials: _____ Date/Time _____

☑ Email (email sent to/on): RKC /9/9/21

Project Manager's response:

Completed By: _____ Date: 9/9/21

Case Narrative

Roux Associates, Inc. 5150 E. Pacific Coast Hwy. Suite 450 Long Beach, CA 90804 Rocio Quinones	Lab Job Number:	450451
	Location:	Shea San Jacinto - 870 N. Sanderson Ave., San Jacinto, CA
	Date Received:	09/13/21

This data package contains sample and QC results for fourteen air samples, requested for the above referenced project on 09/13/21. The samples were received cold and intact.

Volatile Organics in Air by MS (EPA TO-15):

High responses were observed for benzyl chloride and 1,2,4-trichlorobenzene in the ICV analyzed 09/11/21 23:05; affected data was qualified with "b". No other analytical problems were encountered.

Volatile Organics in Air GC (EPA TO-3M):

No analytical problems were encountered.

SAMPLE ACCEPTANCE CHECKLIST

Section 1

Client: Roux Associates Project: Shea San Jacinto

Date Received: 9/13/21 Sampler's Name Present: ☑ Yes ☐ No

Section 2

Sample(s) received in a cooler? ☐ Yes, How many? _____ ☑ No (skip section 2) Sample Temp (°C) (No Cooler): 22.5

Sample Temp (°C), One from each cooler: #1: _____ #2: _____ #3: _____ #4: _____

(Acceptance range is < 6°C but not frozen (for Microbiology samples, acceptance range is < 10°C but not frozen). It is acceptable for samples collected the same day as sample receipt to have a higher temperature as long as there is evidence that cooling has begun.)

Shipping Information: _____

Section 3

Was the cooler packed with: ☐ Ice ☐ Ice Packs ☐ Bubble Wrap ☐ Styrofoam ☐ Paper ☐ None ☐ Other _____

Cooler Temp (°C): #1: _____ #2: _____ #3: _____ #4: _____

Section 4	YES	NO	N/A
Was a COC received?	✓		
Are sample IDs present?	✓		
Are sampling dates & times present?	✓		
Is a relinquished signature present?	✓		
Are the tests required clearly indicated on the COC?	✓		
Are custody seals present?		✓	
If custody seals are present, were they intact?			✓
Are all samples sealed in plastic bags? (Recommended for Microbiology samples)			✓
Did all samples arrive intact? If no, indicate in Section 4 below.	✓		
Did all bottle labels agree with COC? (ID, dates and times)	✓		
Were the samples collected in the correct containers for the required tests?	✓		
Are the containers labeled with the correct preservatives?			✓
Is there headspace in the VOA vials greater than 5-6 mm in diameter?			✓
Was a sufficient amount of sample submitted for the requested tests?	✓		

Section 5 Explanations/Comments

canisters ambient.

Section 6

For discrepancies, how was the Project Manager notified? ☐ Verbal PM Initials: _____ Date/Time _____

☐ Email (email sent to/on): _____ / _____

Project Manager's response:

Completed By: Yeena Soghoyan Date: 9/13/21

Specializing in Environmental Field Services

October 12, 2021

Rocio Quinones
Roux Associates, Inc.
5150 E. Pacific Coast Highway, Suite 450
Long Beach, CA 90804

Dear Rocio:

This letter presents the results of the soil vapor investigation conducted by Optimal Technology (Optimal), for Roux Associates, Inc. on October 11, 2021. The study was performed at 870 N. Sanderson Ave., San Jacinto, California.

Optimal was contracted to perform a soil vapor survey at this site to screen for possible chlorinated solvents and aromatic hydrocarbons. The primary objective of this soil vapor investigation was to determine if soil vapor contamination is present in the subsurface soil.

Gas Sampling Method

At each sampling location, an electric vacuum pump set to draw 0.2 liters per minute (L/min) of soil vapor was attached to the existing well and purged prior to sample collection. Vapor samples were obtained in gas-tight syringes by drawing the sample through a luer-lock connection which connects the sampling probe and the vacuum pump. Samples were immediately injected into the gas chromatograph/purge and trap after collection. New tubing was used at each sampling point to prevent cross contamination.

All analyses were performed on a laboratory grade Agilent model 6890N gas chromatograph equipped with an Agilent model 5973N Mass Spectra Detector and Tekmar LSC 3100 Purge and Trap. A Restek column using helium as the carrier gas was used to perform all analysis. All results were collected on a personal computer utilizing Agilent's MS and chromatographic data collection and handling system.

Quality Assurance

5-Point Calibration
The initial five-point calibration consisted of 20, 50, 100, 200 and 500 ul injections of the calibration standard. A calibration factor on each analyte was generated using a best fit line method using the Agilent data system. If the r^2 factor generated from this line was not greater

than 0.990, an additional five-point calibration would have been performed. Method reporting limits were calculated to be 1-1000 micrograms per cubic meter (ug/m^3) for the individual compounds.

A daily calibration check was performed using a pre-mixed standard supplied by Scotty Analyzed Gases. The standard contained common halogenated solvents and aromatic hydrocarbons (see Table 1). The individual compound concentrations in the standards ranged between 0.025 nanograms per microliter (ng/ul) and 0.25 ng/ul.

TABLE 1

Acetone	Benzene	Bromobenzene	Bromochloromethane
Bromodichloromethane	Bromoform	Bromomethane	2-Butanone (MEK)
n-Butylbenzene	sec-Butylbenzene	tert-Butylbenzene	Carbon Tetrachloride
Chlorobenzene	Chloroethane	Chloroform	Chloromethane
2-Chlorotoluene	4-Chlorotoluene	Cyclohexane	Dibromochloromethane
1,2-Dibromo-3-chloropropane	1,2-Dibromoethane	Dibromomethane	1,2-Dichlorobenzene
1,3-Dichlorobenzene	1,4-Dichlorobenzene	Dichlorodifluoromethane	1,2-Dichloroethane
1,1-Dichloroethane	1,1-Dichloroethene	cis-1,2-Dichloroethene	trans-1,2-Dichloroethene
1,2-Dichloropropane	2,2-Dichloropropane	1,3-Dichloropropane	1,1-Dichloropropene
Ethylbenzene	Freon 113	Hexachlorobutadiene	Isopropylbenzene
p-Isopropyltoluene	Methylene Chloride	4-Methyl-2-Pentanone	Naphthalene
n-Propylbenzene	Styrene	1,1,1,2-Tetrachloroethane	1,1,2,2-Tetrachloroethane
Tetrachloroethene	Toluene	1,2,3-Trichlorobenzene	1,2,4-Trichlorobenzene
1,1,1-Trichloroethane	1,1,2-Trichloroethane	Trichloroethene	Trichlorofluoromethane
1,2,3-Trichloropropane	1,2,4-Trimethylbenzene	1,3,5-Trimethylbenzene	Vinyl Chloride
m/p-Xylene	o-Xylene	Diisopropyl Ether	Ethyl Tert Butyl Ether
MTBE	Tert-Amyl Methyl Ether	Tertiary Butyl Alcohol	Isobutane

Sample Replicates
A replicate analysis (duplicate) was run to evaluate the reproducibility of the sampling system and instrument. The difference between samples did not vary more than 20%.

Equipment Blanks
Blanks were run at the beginning of each workday and after calibrations. The blanks were collected using an ambient air sample. These blanks checked the septum, syringe, GC column, GC detector and the ambient air. Contamination was not found in any of the blanks analyzed during this investigation. Blank results are given along with the sample results.

Purge Volume
The standard purge volume of three volumes was purged in accordance with the July 2015 DTSC/RWQCB Advisory for Active Soil Gas Investigations.

Tracer Gas Leak Test
A tracer gas was applied to the soil gas probes at each point of connection in which ambient air could enter the sampling system. These points include the top of the sampling probe where the tubing meets the probe connection and the surface bentonite seals. Isobutane was used as the tracer gas. No Isobutane was found in any of the samples collected.

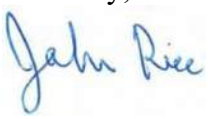
Shut-in Test
A shut-in test was conducted prior to purging or sampling each location to check for leaks in the above-ground sampling system. The system was evaluated to a minimum measured vacuum of 100 inches of water. The vacuum gauge was calibrated and sensitive enough to indicate a water pressure change of at least 0.5 inches.

Scope of Work

To achieve the objective of this investigation a total of 20 vapor samples were collected from 7 locations at the site. Sampling depths, vacuum readings, purge volume and sampling volumes are given on the analytical results page. All the collected vapor samples were analyzed on-site using Optimal's mobile laboratory.

Subsurface Conditions

Subsurface soil conditions offered sampling flows at 0" water vacuum.



Results

During this vapor investigation, two samples contained levels of Chloroform ranging from 13 ug/m^3 to 17 ug/m^3. One sample contained 16 ug/m^3 of Tetrachloroethene (PCE). One sample contained 5 ug/m^3 of Benzene. None of the other compounds listed in Table 1 above were detected above the listed reporting limits. A complete table of analytical results is included with this report.

Disclaimer

All conclusions presented in this letter are based solely on the information collected by the soil vapor survey conducted by Optimal Technology. Soil vapor testing is only a subsurface screening tool and does not represent actual contaminant concentrations in either the soil and/or groundwater. We enjoyed working with you on this project and look forward to future projects. If you have any questions, please contact me at (877) 764-5427.

Sincerely,

John Rice
Project Manager

Executive Summary

Shea Properties (User) retained Roux Associates, Inc. (Roux) to perform a Phase I Environmental Site Assessment (ESA) of the property located approximately 1,800 feet south-southwest of the corner of North Sanderson Avenue and North Ramona Boulevard in the City of San Jacinto, Riverside County, California (the Subject Property). Roux performed this Phase I ESA in general accordance with the American Society for Testing Materials (ASTM) *Standard Practice for Environmental Site Assessments: Phase I Environmental Site Assessment Process* (ASTM E1527-21) in an effort to identify, to the extent feasible, the presence of recognized environmental conditions (RECs) with respect to the Subject Property as defined in ASTM E1527-21. Exceptions to, or deletions from, this practice are described in Section 9.1 of this report.

The Subject Property consists of one approximately 38-acre parcel, identified by Assessor's Parcel Number (APN, 432-030-012), located on the west side of North Sanderson Avenue in an agricultural area of San Jacinto, California. The Subject Property is currently used for agricultural production (unknown row crop). According to historical sources, the Subject Property was vacant land as early as 1901. By at least 1949, agricultural operations began at the Subject Property and are currently present. Since initial agricultural development of the Subject Property, a rotation of row crops, feed crops for livestock, and fallow land have been present at the Subject Property.

On July 28, 2023, Roux visually assessed the Subject Property during the site reconnaissance for potential RECs, including, but not limited to, potential underground storage tanks (USTs), aboveground storage tanks (ASTs), polychlorinated biphenyl (PCB)-containing equipment, hazardous materials storage or handling areas, containerized or bulk wastes, and visual indications of impacted soil.

Roux also performed a records review in an effort to identify RECs in connection with the Subject Property. This records review addressed the Subject Property and surrounding properties. Roux reviewed commercially available records associated with the Subject Property and nearby properties to assess potential concerns associated with the migration of hazardous substances. The records review also included reasonably ascertainable historical data, which can be helpful in identifying the past uses of the Subject Property and surrounding areas, as it may relate to the environmental condition of the Subject Property.

Roux performed interviews and/or file reviews with various government agencies and other parties with possible knowledge of the Subject Property and surrounding properties in an effort to identify current and past uses of the Subject Property and surrounding areas, as they may relate to the environmental condition of the Subject Property.

ASTM E 1527-21 defines a Recognized Environmental Condition (REC) as:

> "The presence of hazardous substances or petroleum products in, on, or at the Subject Property due to a release to the environment; (2) the likely presence of hazardous substances or petroleum products in, on or at the Subject Property due to a release or likely release to the environment; or (3) the presence of hazardous substances or petroleum products in, on or at the Subject Property under conditions that pose a material threat of a future release to the environment. A de minimis condition is not a recognized environmental condition."

A Controlled Recognized Environmental Condition (cREC) as:

> "A recognized environmental condition affecting the Subject Property that has been addressed to the satisfaction of the applicable regulatory authority or authorities with hazardous substances or

petroleum products allowed to remain in place subject to implementation of required controls (for example, activity and use limitations and other property use limitations."

And a Historical Recognized Environmental Condition (hREC) as:

> "A previous release of hazardous substances or petroleum products affecting the Subject Property that has been addressed to the satisfaction of the applicable regulatory authority or authorities and meeting unrestricted use criteria established by the applicable regulatory authority or authorities without subjecting the Subject Property to any controls (for example, activity and use limitations and other property use limitations."

The term recognized environmental condition is not intended to include de minimis conditions that generally do not present a threat to human health or the environment and that generally would not be the subject of an enforcement action if brought to the attention of appropriate governmental agencies.

This Executive Summary provides a brief overview of the findings of this Phase I ESA. Although the Executive Summary is an integral part of a report, it does not substitute for reading the entire report or the appended or referenced documents in order to fully understand the findings and potential environmental concerns associated with the Subject Property.

Recognized Environmental Conditions (RECs)

Based on the information obtained through the performance of this Phase I ESA, Roux identified the following RECs in connection with the current and historical operations at the Subject Property or adjoining properties. To the extent possible, the locations of the RECs are shown in Figure 2. To avoid confusion, all RECs, cRECs, hRECs, and OEFs are numbered sequentially.

> **REC 1 - Former Agricultural Applied Pesticide Area**. Based on a review of historical sources, the Subject Property was developed for agricultural use (row crops and feed crops) as early as 1949, with increased agricultural development noted from at least 1978 to 2016. During the site reconnaissance, row crops were observed on the Subject Property. Agricultural production history at the Subject Property is not currently known. Based on the long term agricultural use, it is likely that agricultural chemicals, such as pesticides, herbicides, and fertilizers, have been used on-site, and the potential for impacts from agricultural chemicals to on-site soils is considered a REC.

Controlled Recognized Environmental Conditions (cRECs)

Roux did not identify known or suspected cRECs in connection with the current and historical operations at the Subject Property or adjoining properties.

Historical Recognized Environmental Conditions (hRECs)

Roux did not identify known or suspected hRECs in connection with the current and historical operations at the Subject Property or adjoining properties.

Other Environmental Features (OEFs)

Roux did not identify known or suspected OEFs in connection with the current and historical operations at the Subject Property or adjoining properties.

1. Introduction

Roux Associates, Inc. (Roux) completed this Phase I Environmental Site Assessment (ESA) of the property located approximately 1,800 feet south-southwest of the corner of North Sanderson Avenue and North Ramona Boulevard in the City of San Jacinto, Riverside County, California (the Subject Property). The Subject Property location is shown in Figure 1 and the Subject Property and vicinity is shown in Figure 2. Roux performed this Phase I ESA in compliance with the scope and limitations of American Society for Testing Materials (ASTM) E1527-21 and the terms and conditions of Roux' proposal dated May 24, 2023. Roux conducted this Phase I ESA for the benefit of Shea Properties (the User).

The following sections of this report present our Phase I ESA findings and conclusions. A glossary containing terms and definitions presented in ASTM E1527-21 is included in Appendix A – Glossary of Terms. Other appendices presented at the end of the report include historical topographic maps, historical aerial photographs, regulatory records review documentation, applicable historical records, and personnel qualifications.

1.1 Purpose

The purpose of this Phase I ESA is to identify and report, to the extent feasible, recognized environmental conditions (RECs) with respect to the Subject Property. Performing a Phase I ESA in general compliance with ASTM E 1527-21 may enable a User to satisfy one of the requirements to qualify for the innocent landowner, contiguous property owner, or bona fide prospective purchaser limitations on Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) liability. That is, the practice that constitutes one of the requirements for "all appropriate inquiry into the previous ownership and uses of the property consistent with good commercial or customary practice" as defined in 42 USC Section 9601(35) (B).

1.2 Scope of Services

The scope of services for this Phase I ESA included, but was not limited to, the activities listed below.

- A review of reasonably ascertainable and practicably reviewable topographic maps, historical aerial photographs, and city directories, if available, to investigate current and past uses of the Subject Property and surrounding properties;
- A review of specific government lists pursuant to ASTM Standard E 1527-21 regarding environmental activities for the Subject Property and local area properties;
- A review of recorded land title records, building, assessors, and fire department records, for permits, citations, and reports connected to the Subject Property that were reasonably ascertainable, practicably reviewable, and publicly available within reasonable time and cost;
- An inspection by an environmental professional to investigate the current use of the Subject Property and to identify environmental concerns including but not limited to, the presence of hazardous substances or petroleum products, wastes, underground storage tanks (USTs), aboveground storage tanks (ASTs), or other environmental concerns;
- Interviews with available representatives of the owner of the Subject Property, occupants, and local government officials by an environmental professional; and
- Preparation of this Phase I ESA report.

Roux initiated this Phase I ESA pursuant to receipt of written authorization to proceed on May 24, 2023.

1.3 Standard of Care

Roux conducted this Phase I ESA using a defined scope of services considered appropriate and agreed upon by all parties on the date the service was authorized, unless the scope of services or the methods used were later modified, in writing, and accepted by all parties prior to performance. Roux conducted this Phase I ESA in accordance with generally accepted practices in a manner consistent with that level of care exercised by other members of our profession in the same locality and under similar conditions of time and accessibility of improvements and information. No other representations, expressed or implied, and no warranty or guarantee is included or intended to be part of this Phase I ESA.

Please note that the scope of services performed in execution of this assessment may not be appropriate to satisfy the needs of other parties. We, therefore, are not responsible for independent conclusions, opinions, or recommendations of others based on our assessment. Furthermore, this Phase I ESA relates to the environmental conditions of the Subject Property and does not address issues raised in transactions such as business risk, purchase of business entities, or interests therein, or of their assets, that may well involve environmental liabilities pertaining to properties previously owned or operated or other off-site liabilities.

Additionally, the findings of this Phase I ESA are based on Roux' observations, inquiries, and historical research using reasonably ascertainable and practically reviewable information obtained within reasonable time and cost constraints. Roux does not represent that this Phase I ESA is an exhaustive investigation that reflects the findings of all of the information available for the Subject Property, nor is it representative of future Subject Property conditions. If additional information is generated from the Subject Property, it should be provided to Roux so that we may evaluate its impact on our conclusions. As such, activities or episodes that transpire subsequent to this Phase I ESA are not considered in this assessment. It is not intended that a Phase I ESA in accordance with ASTM E1527-21 be an exhaustive assessment of a property nor can it wholly eliminate uncertainty regarding the potential for *recognized environmental conditions* in connection with a property.

1.4 Assumptions

This Phase I ESA Report, including the exhibits attached hereto, describes the results of Roux' investigation to identify the presence of *recognized environmental conditions* connected with the Subject Property in accordance with ASTM E1527-21, as allowed by and consistent with the regulatory requirements of the All Appropriate Inquiry Rule, 40 CFR Part 312, Amendment to Standards and Practices for All Appropriate Inquires Under CERCLA, Final Rule, published December 30, 2013 (AAI Rule). Specifically, the preamble to the amended AAI Rule states:

> *The Environmental Protection Agency (EPA) today is taking final action to amend the standards and practices for conducting all appropriate inquiries under the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) to reference a standard practice recently made available by ASTM International, a widely recognized standards development organization. Specifically, this final rule amends the "All Appropriate Inquiries Rule" at 40 CFR Part 312 to reference ASTM International's E1527–13 "Standard Practice for Environmental Site Assessments: Phase I Environmental Site Assessment Process" and make clear that persons conducting all appropriate inquiries may use the procedures included in this standard to comply with the All Appropriate Inquiries Rule*[1].

[1] Federal Register: December 30, 2013 (Volume 78, Number 250) Page 79319

As of February 13, 2023, the EPA indicated that the updated standard ASTM E1527-21 is now AAI compliant. While ASTM E1527-21 is now the current standard, the previous standard (ASTM E1527-13) is still AAI compliant until February 13, 2024.

One of the requirements that a person acquiring real property must meet in order to qualify for either the innocent landowner, contiguous owner, or bona fide prospective purchaser (collectively hereinafter "Prospective Purchaser") defense to liability under the federal Comprehensive Environmental Response, Compensation, and Liability Act of 1980, as amended by the Superfund Amendments and Reauthorization Act of 1986, and the Small Business Liability Relief and Brownfields' Revitalization Act of 2002, 42 U.S.C. 9601-9675 (collectively referred to hereafter as "CERCLA") is that person must conduct all appropriate inquiries into the previous ownership and uses of the property in conformance with the AAI Rule (or the ASTM E1527-21) prior to acquisition of the property. The User has acknowledged that, under the AAI Rule, Roux' performance of this Phase I ESA in accordance with ASTM E1527-21 will not alone result in the User satisfying all requirements of the AAI Rule and will not in itself provide a defense to CERCLA liability. The User has acknowledged that the AAI Rule also requires that the Prospective Purchaser undertake certain additional inquiries and post-acquisition activities to satisfy the CERCLA AAI requirements. Accordingly, Roux makes no guarantees or warranties, expressed or implied, regarding this Phase I ESA, including without limitation, that this Phase I ESA will qualify the User for a defense to CERCLA liability.

Roux has performed this Phase I ESA in a professional manner using that degree of skill and care exercised for similar projects under similar conditions by reputable and competent environmental consultants. Professional judgments expressed herein are based on the facts currently available to Roux.

The AAI Rule requires, and the conclusions and recommendations stated herein represent, the application of a variety of engineering and technical disciplines to material facts and conditions associated with the Subject Property. As such, these conclusions and recommendations are based on subjective interpretations and the exercise of discretion based on the facts available to Roux and conditions at the time of the performance of this Phase I ESA. Many of these facts and conditions are subject to change over time. Accordingly, the conclusions and recommendations must be considered within this context.

The User has agreed that Roux shall not be responsible for conditions or consequences arising from relevant facts that were concealed, withheld, or not fully disclosed at the time this Phase I ESA was performed. To the extent practicable, Roux has identified data gaps, and has evaluated the potential significance of such data gaps. Recommendations to address those data gaps are presented herein and are based on the data available at the time of the performance of this Phase I ESA. Implementation of the recommendations may not fully address the data gaps, and the information obtained from execution of those recommendations may alter and/or modify the interpretation of the Subject Property conditions and conclusions, herein. This Phase I ESA does not include consideration of matters specifically excluded by ASTM E1527-21, including but not limited to, asbestos-containing building materials, radon, lead-based paint, lead in drinking water, wetlands, regulatory compliance, and mold unless specifically identified herein. Emerging contaminants that are not defined as hazardous substances under CERCLA including, but not limited to per- and polyfluoroalkyl substances (PFAS) are outside the scope of the Phase I ESA. This Phase I ESA does not include the completion of searches for recorded environmental liens.

Roux has not collected any soil and/or groundwater samples on the Subject Property for Phase I purposes, and is relying on information presented by others, often in preliminary, draft, or verbal form. By referencing

this information, Roux does not accept responsibility for the accuracy of the underlying data, sampling methods, laboratory analysis, or documentation.

This Phase I ESA Report should not be considered a legal interpretation of existing environmental laws and regulations. This Phase I ESA was conducted with a reasonable degree of inquiry to identify *recognized environmental conditions*, but uncertainty is not eliminated. No Phase I ESA can wholly eliminate uncertainty regarding the potential for *recognized environmental conditions* in connection with a property. The Phase I ESA process is intended to reduce, but not eliminate, the uncertainty involved with identifying *recognized environmental conditions*.

This Phase I ESA Report is not an appraisal or value judgment of the Subject Property. The User has agreed that Roux shall not be liable for any use of this Phase I ESA Report as an appraisal or value judgment of the Subject Property.

This Phase I ESA Report has been prepared for the exclusive use of the User for specific application to the Subject Property covered by this Phase I ESA Report. The User has agreed that any third-party use of this Phase I ESA Report, upon disclosure by the User, is the sole responsibility and at the sole liability of the User.

1.5 User Reliance

No additional parties may use the information contained in this report without obtaining the written permission of Roux or the User. Roux' duties and obligations extend to the User and to no other party. Roux' duties and obligations to the User are not transferable to persons, corporations, or organizations without the express written consent of the User and Roux. The User may rely upon the information provided in this Phase I ESA report for a period of 180 days from the earliest of the previously listed components. After 180 days, this Phase I ESA should be updated in accordance with ASTM E1527-21 guidance. Roux will not be liable for any consequential damages arising from the use of this report for other than its intended purpose, for use of this report beyond 180 days of its issue date, or from unauthorized use by third parties. Dates components used in the preparation of this Phase I ESA were obtained are summarized below:

Phase ESA Component Dates		
Component	**Date Obtained**	**Expiration Date**
Radius Report	May 31, 2023	November 27, 2023
Knowledgeable Person Interview	August 10, 2023	February 6, 2024
Site Reconnaissance	July 28, 2023	January 24, 2023

This Phase I ESA report must be read and interpreted as a whole and can only be considered representative of the conditions of the Subject Property as of the date of our site reconnaissance described herein. Roux makes no representation whatsoever concerning the condition of the Subject Property beyond the date of our site reconnaissance described herein. Individual sections and appendices of this report are dependent on the balance of this report, and on the terms, conditions, and stipulations contained in the proposal and written amendments accepted by Roux.

2. Subject Property Description

2.1 Subject Property Location and Description

Subject Property Information	
Legal Description	Lot 128 MB 008/357 SD San Jacinto Rancho
Address	No assigned addresses currently exist
City	City of San Jacinto
County	Riverside
State	California
Location	Approximately 1,800 feet south-southwest of the corner of North Sanderson Avenue and North Ramona Boulevard
Assessor's Parcel Number (APN)	432-030-012
Site Acreage (per Los Angeles County Assessor Website)	38.15 acres
Site Occupant(s)	None
On-site Operations	Agricultural production (unknown row crops)
Description of On-site Structures	No structures currently occupy the Subject Property
Site Paving	Unpaved
Site Vicinity	Agricultural (dry farming, animal grazing pastures, dairies), commercial, and residential use

Refer to Section 5.0 for a detailed description of the current condition of the Subject Property and operations.

2.2 Vicinity General Characteristics

The facilities and improvements which are adjoining to the Subject Property are provided in the following table. Selected adjoining and nearby properties are shown in Figure 2.

Direction from Subject Property	Improvements / Use (Addresses)
North	Agricultural land
East	North Sanderson Avenue followed by a single-family residential dwelling (1727 North Sanderson Avenue) and agricultural land
South	Agricultural land
West	Agricultural land

2.3 Past Use of the Subject Property

The Subject Property was vacant land as early as 1901. By at least 1949, agricultural operations began at the Subject Property. Since initial agricultural development of the Subject Property, a rotation of row crops,

feed crops for livestock, and fallow land have been present at the Subject Property. At the time of site reconnaissance, row crops were present at the Subject Property.

2.4 Physical Setting

Roux obtained and reviewed published, reasonably ascertainable information concerning the physical setting of the Subject Property. The following is a summary of the information reviewed from those physical setting sources.

Physical Setting Summary	
United States Geological Survey (USGS) Topographic Map	Lakeview, California Quadrangle
Approximate Subject Property Elevation / Source	1,465 feet above mean sea level (msl) / Lakewood, California (2018) 7.5-minute quadrangle topographic map published by the USGS
Nearest Surface Water Features / Approximate Distance	A pond associated with the California Equine Retirement Foundation is located approximately 4,500 feet south-southeast, reclamation ponds associated with the San Jacinto Valley Regional Reclamation Facility are located approximately 5,100 feet to the south and south-southwest, the San Jacinto Reservoir is located approximately 6,050 feet to the southeast, and the San Jacinto River is located approximately 7,000 feet to the north of the Subject Property.
Regional Geology / Source	Quaternary deposits: alluvium, lake, playa and terrace, consolidated and semi-consolidated / California Department of Conservation, 2010 Geologic Map of California
Subject Property Topography / Source	Generally flat with a gradual slope to the north / Site observation and USGS topographic map
Hydrogeological Region / Source	Located along the eastern portion of the San Jacinto Groundwater Basin / *California Department of Water Resources Bulletin 118, Update 2003 and Interim Update 2016*
Depth to Groundwater / Source	Perched groundwater zones in the site vicinity were reported to be approximately 11 to 13 feet below ground surface (bgs) / Monitoring well installation report for a facility approximately 2,600 feet north-northeast of the Subject Property (Leighton, 2009)
Groundwater Gradient Direction / Source	Groundwater in the site vicinity is reported to flow to the southwest with a hydraulic gradient of approximately 0.004 feet per foot / Monitoring well installation report for a facility approximately 2,600 feet north-northeast of the Subject Property (Leighton, 2009)
On-site or Nearby Soils	Soils in the site vicinity are reported to be silty sands to a depth of approximately 16 feet bgs, fine-grained sand from 16 to 20 feet bgs, and silty sand from 20 feet bgs to a total depth explored of 22 feet bgs / Monitoring well installation report for a facility approximately 2,600 feet north-northeast of the Subject Property (Leighton, 2009)

3. Sources of Information

Sources of information utilized in preparing this Phase I ESA report included historical topographic maps; historical aerial photographs; a walkover survey of the Subject Property and adjoining properties; in-person discussions with User and tenant personnel; a review of records available at selected local and state regulatory agencies; a review of databases maintained by local, state, and federal government agencies; and other records available from commercial and online sources.

3.1 Historical Sources

To help understand the history of the Subject Property and adjoining properties, historical sources were obtained from Environmental Data Resources, Inc. (EDR), of Shelton, Connecticut. The sources and locations within the Appendices are provided in the table below.

EDR Historical Sources		
Historical Range	**Source**	**Appendix**
1901 – 2018	U.S. Geological Survey Topographic Maps	B
1938 – 2020	EDR Aerial Photographs "Decade Package"	C
No Available Coverage	EDR "Certified Sanborn® Map Report"	D
1971 – 2020	EDR "City Directory Image Report"	E

3.2 Government Databases

To document potential sources of contamination at or near the Subject Property, a government records search was conducted by EDR. The search included local, state, and federal records for the Subject Property and for other properties within ASTM-standard distances of the Subject Property. The records search is summarized in Section 8.0 and a copy of "The EDR Radius Map™ Report with GeoCheck®," dated May 31, 2023, is included in its entirety as Appendix F. As recommended by ASTM, all but a few of the databases searched were "current," i.e., had been updated within 90 days prior to the search date.

3.3 Site Reconnaissance

On July 28, 2023, Roux personnel conducted a reconnaissance of the Subject Property. During the site reconnaissance, Roux representative Ms. Audrey Clark was able to access all areas of the Subject Property, which was used for agricultural production at the time of the reconnaissance. The observations made during the site reconnaissance are discussed in Section 5.0 and throughout the report. A photographic log of the site reconnaissance is included as Appendix G.

3.4 Interviews

On August 10, 2023, Roux contacted Mr. Jay Pierce, a representative of the Subject Property ownership, via telephone for an interview regarding the history of the Subject Property. Mr. Pierce has been associated with the Subject Property since approximately 2001 and was not aware of the current type of crop being grown on-site. Mr. Pierce confirmed that crop production has varied over the years and has included watermelon

and grain for animal feed. Mr. Pierce referred to a previous Phase I ESA report which is discussed below in Section 6.0.

No previous Subject Property owners/operators were available for an interview. This data gap is not considered significant due to sufficient information regarding Subject Property history available from EDR historical documents and public records requests.

3.5 User Provided Information

ASTM E1527-21 provides an optional User Questionnaire to present select User-provided information that can assist in identifying possible RECs in connection with the Subject Property. According to ASTM E1527-21, these tasks do not require the technical expertise of an environmental professional and the environmental professional generally does not perform these tasks. Roux administered the optional questionnaire to the User at the beginning of this Phase I ESA to assist them with these tasks; however, the completed questionnaire has not been returned to Roux as of this report date.

3.6 Regulatory Agencies

Roux contacted governmental agencies for reasonably ascertainable information concerning environmental conditions at the Subject Property. Roux contacted or reviewed information from the agencies provided in the following table. Refer to Appendix H – Pertinent Historical Documentation for copies of the records reviewed. A summary of the information gathered from the regulatory agencies is provided in the table and details regarding the records were incorporated into applicable sections as noted.

Agency	Date Requested / Accessed	Response Date	Description of Records	Section Discussed
Federal				
U.S. Environmental Protection Agency (EPA) – FOIAonline	5/30/2023	Pending	A response has not been received as of this report date.	N/A
National Pipeline Mapping System (NPMS) Online Database	5/31/2023	N/A	No pipelines were found within 1,000 feet of the Subject Property.	N/A
State				
State Water Resources Control Board (SWRCB): GeoTracker Online Database	5/31/2023	N/A	No records were associated with the Subject Property and no records were identified within 1,000 feet of the Subject Property.	N/A
SWRCB: Storm Water Multiple Application and Report Tracking System (SMARTS) Online Database	5/31/2023	N/A	No records were associated with the Subject Property.	N/A
Department of Toxic Substances Control (DTSC) Sacramento Office	5/30/2023	6/1/2023	No records were associated with the Subject Property.	N/A
DTSC Chatsworth Office	5/30/2023	5/31/2023	No records were associated with the Subject Property.	N/A
DTSC Cypress Office	5/30/2023	6/6/2023	No records were associated with the Subject Property.	N/A
DTSC: EnviroStor Online Database	5/31/2023	N/A	No records were associated with the Subject Property. One EnviroStor record was listed on an adjoining property west of the Subject Property. The Proposed High School at the Villages of San Jacinto facility is listed as a DTSC Site Cleanup Program and discussed below in Section 7.1.2.	7.1.2
DTSC: Hazardous Waste Tracking System (HWTS) Online Database	5/31/2023	N/A	No records were associated with the Subject Property.	N/A

4. Subject Property History

This section documents the history of the Subject Property and adjoining properties and describes current conditions and existing or former environmental features.

4.1 Subject Property History

The history of the Subject Property and, to a lesser extent, the surrounding area, including previous land use, has been compiled based on information from the exhaustive list of sources provided in Section 3.

Summary of Historical Sources				
Decade	**Year**	**Source**	**Subject Property Description**	**Vicinity Description**
Predevelopment History				
1900s	1901	Historical Topographic Map: Elsinore / San Jacinto (30-minute)	The Subject Property appear to be undeveloped vacant land.	Adjoining properties appear as vacant land. Roads are depicted to the north (currently Ramona Expressway) and east (currently Ramona Boulevard). Minor homesteads or residential dwellings are depicted during this period.
1920s	No sources available.			
1930s	1938	EDR Aerial Photograph	The Subject Property is depicted as undeveloped vacant land.	The Colorado River Aqueduct is depicted to the north of the Subject Property.
Early Agricultural Use				
1940s	1943	Historical Topographic Map: Perris / Banning (15-minute)	No significant changes from prior topographic maps.	No significant changes from prior Subject Property history except for some additional residential dwellings to the north and east and the appearance of a dirt road in the Subject Property's vicinity on the west.
	1948	Historical Topographic Map: Banning (15-minute)	The Subject Property is located in an unmapped region of the topographic map.	No significant changes from prior topographic maps.

Summary of Historical Sources				
Decade	**Year**	**Source**	**Subject Property Description**	**Vicinity Description**
	1949	EDR Aerial Photograph	The Subject Property is depicted as developed by agricultural related activities (row crops). An unpaved road is depicted along the eastern boundary of the Subject Property.	Adjoining properties are depicted as developed by row crops.
1950s	1953	Historical Topographic Map: Lakeview / San Jacinto (7.5-minute)	The Subject Property is depicted as vacant land (identified as developed by row crops in aerial photos). A dirt road is depicted to run along the eastern boundary of the of the Subject Property's parcel.	The Colorado River Aqueduct is present to the north of the Subject Property. The San Jacinto Reservoir is depicted approximately 1-mile southeast of the Subject Property.
		EDR Aerial Photograph	No significant changes from prior aerial photographs.	No significant changes from prior aerial photographs.
	1956	Historical Topographic Map: Lakeview / San Jacinto (7.5-minute)	The Subject Property is located in an unmapped region of the topographic map.	No significant changes from prior topographic maps.
1960s	1961	EDR Aerial Photograph	No significant changes from prior aerial photographs.	Adjoining properties during this period are depicted as being developed by duck ponds to the north and east of the Subject Property. No other configurational changes were noted.
	1967	EDR Aerial Photograph	No significant changes from prior aerial photographs.	No significant changes from prior aerial photographs.
1970s	1967 / 1972	Historical Topographic Map: Lakeview / San Jacinto (15-minute)	No significant changes from prior topographic maps.	No significant changes from prior topographic maps.
	1975	EDR Aerial Photograph	No significant changes from prior aerial photographs.	No significant changes from prior aerial photographs.
	1978	EDR Aerial Photograph	No significant changes from prior aerial photographs.	No significant changes from prior aerial photographs.
	1979	Historical Topographic Map: Lakeview / San Jacinto (7.5-minute)	No significant changes from prior topographic maps.	Asphalt surfacing of the former identified unpaved road on the eastern elevation of the Subject Property (North Sanderson Avenue).

Summary of Historical Sources				
Decade	**Year**	**Source**	**Subject Property Description**	**Vicinity Description**
1980s	1985	EDR Aerial Photograph	No significant changes from prior aerial photographs.	Adjoining properties to the north and to the east following North Sanderson Avenue appear to be vacant land covered in native vegetation. Adjoining properties to the west and south appear to be agriculturally developed by row crops as identified previously.
	1989	EDR Aerial Photograph	No agricultural activities appear to be present. The Subject Property is vacant.	Limited row crops appear to the east following North Sanderson Avenue. The other adjoining properties have had no significant changes from what has been identified previously.
1990s	1996	EDR Aerial Photograph	Agricultural activities resume with row crops.	Agricultural fields to the east following North Sanderson Avenue appear to be dormant as well as to the west. Row crops are developed on the northern and southern adjoining properties. Potential construction is noted to the northeast across from North Sanderson Avenue.
		Historical Topographic Map: San Jacinto (7.5-minute)	The Subject Property is located in an unmapped region of the topographic map.	No significant changes from prior topographic maps.
2000s	2002	EDR Aerial Photograph	No agricultural activities appear to be present. The Subject Property is vacant.	Agricultural fields to the east following North Sanderson Avenue have had no significant changes. Adjoining properties to the north, south and appear to be fallow land. Limited row crops are depicted on the western adjoining property.
	2006	EDR Aerial Photograph	No significant changes from prior aerial photographs.	No significant changes from prior history except the western adjoining property, which appears to be dormant.
	2009	EDR Aerial Photograph	No significant changes from prior aerial photographs.	No significant changes from prior aerial photographs.

Summary of Historical Sources				
Decade	**Year**	**Source**	**Subject Property Description**	**Vicinity Description**
2010s	2012	Historical Topographic Map: Lakeview / Sab Jacinto (7.5-minute)	No significant changes from prior topographic maps.	No significant changes from prior topographic maps.
	2012	EDR Aerial Photograph	No significant changes from prior aerial photographs.	No significant changes from prior aerial photographs.
	2015	Historical Topographic Map: Lakeview / San Jacinto (7.5-minute)	No significant changes from prior topographic maps.	No significant changes from prior topographic maps.
	2016	EDR Aerial Photograph	No significant changes from prior aerial photographs.	No significant changes from prior aerial photographs.
	2018	Historical Topographic Map: Lakeview / San Jacinto (7.5-minute)	No significant changes from prior topographic maps.	No significant changes from prior topographic maps.
2020s	2020	EDR Aerial Photograph	No significant changes from prior aerial photographs; however, the Subject Property appears to have active agricultural growth.	No significant changes from prior aerial photographs.

The Subject Property continued to be used for agricultural purposes (row crops). Environmental concerns associated with historical and current agricultural operations are discussed below in Section 5.2.

5. Current Subject Property Conditions

A Roux representative conducted a reconnaissance of the Subject Property and surrounding areas on July 28, 2023. During the Subject Property visit, Roux representative, Ms. Audrey Clark, observed the Subject Property and adjoining properties from reasonably accessible locations on the Subject Property and public thoroughfares. During the site reconnaissance, the weather was clear, and the temperature was approximately 100° Fahrenheit. The following sections summarize observations during the inspection. Roux documented the site reconnaissance with photographs which are provided in Appendix G.

5.1 Site Reconnaissance

The Subject Property is currently agricultural land used for growing row crops. Roux observed a PVC-piping irrigation system used at the Subject property and surrounding properties. North Sanderson Avenue is located immediately east of the Subject Property. The adjoining properties to the north, east, south, and west are mainly agricultural and/or fallow land. To the east, there is a single-family residence and agricultural land.

5.2 Phase I ESA Observations

During the site reconnaissance, Roux personnel attempted to identify any environmental features that may be relevant in the context of the Phase I ESA. The features identified are summarized in the table below. Any such features are discussed in the following subsections.

Feature	Observed on the Subject Property	Observed on an Adjoining Property
Areas of stressed vegetation		
Areas which receive flood or storm water from potentially contaminated areas		
Air Compressor Vent Discharges		
Chemical Storage and/or Use		
Drainage Swales and Culverts		
Discharge Areas		
Discolored or Spill Areas		
Drums (55 Gallons or Larger)		
Electrical Transformers		
Former Agricultural Applied Pesticide Area	X	X
Hydraulic Lifts		
Incinerators		
Landfills or Landfarms		

Feature	Observed on the Subject Property	Observed on an Adjoining Property
Loading and Unloading Areas		
Non-Contact Cooling Water Discharge		
Oil-Water Separator(s)		
Open Areas Away from Production Areas		
Process Area Sinks and Piping		
Rail Cars/Railroad Spurs		
Septic Systems Leach Fields or Seepage Pits		
Silos		
Sprayfields		
Storm Sewer and Spill Containment Collection System		
Storm Water Detention Pond		
Surface Impoundments and Lagoons		
Underground / Aboveground Storage Tanks and Associated Piping		
Waste Piles		

5.2.1 Former Agricultural Applied Pesticide Area

The Subject Property has been primarily developed for agricultural purposes (row crops and feed crops) since 1949. At the time of Roux's site reconnaissance, the Subject Property was primarily developed with row crops (unknown crop). According to a representative of the Subject Property owner, agricultural production at the site has included watermelon and grain (likely wheat). Agricultural production history at the Subject Property is not currently known. Based on the long term agricultural use, it is likely that agricultural chemicals, such as pesticides, herbicides, and fertilizers, have been used on-site, and the potential for impacts from agricultural chemicals to on-site soils is considered a REC.

6. Summary of Key Previous Investigations

The following sections provide a summary of previous environmental investigations at the Subject Property. Previous environmental investigation reports are included in Appendix H.

Roux conducted previous investigations at the southwest adjoining property in 2021. The off-site investigations were prepared under separate covers and no environmental issues were identified that would be considered a REC to the Subject Property in the context of this Phase I ESA.

6.1 Phase I ESA (South Shore, 2021)

South Shore Testing and Environmental (South Shore) conducted a Phase I ESA of the Subject Property in 2021 on behalf of the current property owner, J.D. Pierce Company, Inc. At the time of the assessment, the Subject Property was vacant agricultural land and proposed to be redeveloped for residential use. South Shore identified the potential presence of pesticides in soil from historical agricultural use as a REC and recommended further investigation.

According to Mr. Pierce, while the previous site assessment recommended further investigation into the presence of pesticides in shallow soil, no such subsurface investigations have been conducted to date.

7. Database Records Review

7.1 Standard Environmental Record Sources

According to ASTM Standard E1527-21, the purpose of reviewing regulatory records is to obtain and review records that will help identify *recognized environmental conditions* in connection with the Subject Property. In addition, some records to be reviewed pertain not only to the Subject Property, but also to properties within an additional "approximate minimum search distance" in order to help assess the likelihood of problems from migrating hazardous substances or petroleum products. The basis of the "approximate minimum search distance" is the Subject Property boundary.

Roux retained EDR of Shelton, Connecticut to provide an ASTM Radius Map Report (EDR Report) for this Subject Property. This report is a computerized search of select state and federal environmental databases that identify various properties with a record of environmental activity. Roux reviewed the report and summarized the relevant findings in the following sections. A copy of the compiled EDR Report has been included as Appendix F. The EDR report includes a detailed description of each of the databases searched, providing a summary of the type of information provided by each. A summary of Roux' review of the EDR Report listings is provided in Table 1.

The following section describes the findings of the database search. Roux used professional judgement in determining which EDR-listed sites to include in the narrative of this report. Facilities adjoining the Subject Property were included due to their proximity to the Subject Property and the potential for surface water discharges (e.g., storm water runoff, surface water effluent discharges) to enter the Subject Property or through the migration of groundwater. Sites with listings indicative of a release (e.g., SHWS, LUST, RELEASE) are likewise discussed below. Non-adjoining facilities with database listings not necessarily indicative of a release (hazardous waste generator, FINDS, ECHO, NPDES, HAZNET, AST, or UST) will not be discussed unless considered potentially relevant in context of the Phase I ESA.

7.1.1 Subject Property (Target Property)

No listings for the Subject Property were identified in the EDR Report.

7.1.2 Adjoining and Nearby Properties

Discussions of adjoining and nearby properties of potential environmental concern as noted in Table 1 are provided below.

- **Proposed High School at the Villages of San Jacinto (Ramona Boulevard and Cawston Avenue).** The Proposed High School at the Villages of San Jacinto (Proposed High School) was located approximately 0.15 mile west of the Subject Property and is listed on the ENVIROSTOR and SCH databases. The ENVIROSTOR listing indicates soil samples, composite surface soil samples, and discrete soil samples were collected from the property to determine potential threat to public health and/or the environment related to former agricultural use of the site. A letter of "No Further Action" was given on September 24, 2008. Based on the "No Further Action" letter and the lack of additional investigation, the Proposed High School property is not considered an environmental concern in the context of the Phase I ESA.

- **San Jacinto Mobil (2070 North Sanderson Avenue).** The San Jacinto Mobil facility is located approximately 0.5 mile northeast of the Subject Property and is listed on the LUST (Leaking Underground Storage Tank), CORTESE, and CERS databases. The LUST database indicates there is a cleanup case for diesel, gasoline, waste oil, motor oil, hydraulic oil, and lubricating oil in

groundwater. According to groundwater monitoring reports, samples collected towards the direction of the Subject Property were non-detectable or had low detections of chemicals of concern (Leighton, 2009). On May 27, 2010, the facility was granted case closure by RCDEH. Due to the closure status and low detections, the San Jacinto Mobil facility is not considered an environmental concern in the context of the Phase I ESA.

7.1.3 Orphan Subject Properties

The EDR Report includes a section addressing "Orphan" sites. Orphan listings are sites, which, due to incomplete geographic location data, incomplete address information or incorrect address information, cannot be plotted correctly. The database report identified no unmapped facilities.

8. Findings

Roux has performed this Phase I ESA in general compliance with the scope and limitations of ASTM Standard Practice E1527-21. Roux separated the findings of this assessment into the following four categories: *recognized environmental conditions*, *controlled recognized environmental conditions*, *historical recognized environmental conditions* and *other environmental features*.

8.1 Data Gaps

During conduct of this ESA, the following data gaps, as defined in ASTM Standard E1527-21 were identified:

- The timing of the report did not allow for all contacted agencies to respond to the records requests issued. This data gap is not considered significant due to sufficient information available from previous environmental reports, the EDR report, and city, county, and state websites.
- Previous Subject Property owners/operators were not available for an interview. This data gap is not considered significant due to sufficient information regarding Subject Property history available from EDR historical documents and FOIA requests.

8.2 Recognized Environmental Conditions

Based on the information obtained through the performance of this ESA, Roux identified the following RECs in connection with the current and historical operations at the Subject Property or adjoining properties. To the extent possible, the locations of the RECs are shown in Figure 2. To avoid confusion, all RECs, cRECs, hRECs, and OEFs are numbered sequentially.

REC 1 - Former Agricultural Applied Pesticide Area. Based on a review of historical sources, the Subject Property was developed for agricultural use (row crops and feed crops) as early as 1949, with increased agricultural development noted from at least 1978 to 2016. During the site reconnaissance in July 2023, row crops were observed on the Subject Property. Agricultural production history at the Subject Property is not currently known. Based on the long term agricultural use, it is likely that agricultural chemicals, such as pesticides, herbicides, and fertilizers, have been used on-site, and the potential for impacts from agricultural chemicals to on-site soils is considered a REC.

8.3 Controlled Recognized Environmental Conditions

Roux did not identify known or suspected cRECs in connection with the current and historical operations at the Subject Property or adjoining properties.

8.4 Historical Recognized Environmental Conditions

Roux did not identify known or suspected hRECs in connection with the current and historical operations at the Subject Property or adjoining properties.

8.5 Other Environmental Features

Roux did not identify known or suspected OEFs in connection with the current and historical operations at the Subject Property or adjoining properties.

10. Signature of Environmental Professional

Roux performed this assessment in accordance with the generally accepted practices for environmental assessments at the time of implementation. Roux made a reasonable effort to ensure that the information presented in this report is materially complete and accurate.

Roux completed a Phase I ESA in general compliance with the scope and limitations of ASTM Practice E1527-21 of the property located along North Sanderson Avenue, approximately 1,800 feet south-southwest of the corner of North Sanderson Avenue and North Ramona Boulevard, San Jacinto, Riverside County, California.

“We declare that, to the best of our professional knowledge and belief, we meet the definition of Environmental professional as defined in §312.10 of 40 CFR 312” and,

“We have the specific qualifications based on education, training, and experience to assess a property of the nature, history, and setting of the Subject property. We have developed and performed the all appropriate inquiries in conformance with the standards and practices set forth in 40 CFR Part 312.”

Roux performed this Phase I ESA by, or under direct supervision of, the undersigned environmental professionals. Copies of professional profiles for the undersigned environmental professionals and report preparers are included in Appendix I.

Respectfully Submitted,

Re: Phase II Subsurface Investigation Letter Report, J.D. Pierce Property, Approximately 38-Acre Property, North Sanderson Avenue, San Jacinto, Riverside County, California

Dear Mr. Perales:

Roux Associates, Inc. (Roux) has prepared this Phase II Subsurface Investigation Letter Report (Phase II Report) to Shea Properties (Client), to summarize the findings of shallow soil sampling conducted at the 38-acre vacant property located approximately 1,800 feet south-southwest of the corner of North Sanderson Avenue and North Ramona Boulevard in the City of San Jacinto, California (Site; Figure 1). Roux completed a Phase I Environmental Site Assessment (ESA), dated August 30, 2023, which identified a recognized environmental concern (REC) associated with potential pesticide impacts to shallow soils from agricultural (row crop) use as early as 1949, with increased agricultural use noted from at least 1978 to 2016.

To address the identified environmental concern, Roux collected composite and discrete soil samples from twelve locations (quadrants) across the Site to establish baseline conditions and identify potential impacts in the shallow soil associated with historical agricultural use. Soil sampling was conducted in general accordance with the California Department of Toxic Substances Control (DTSC) *Interim Guidance for Sampling Agricultural Properties*, dated August 7, 2008.

BACKGROUND

The Site consists of approximately 38 acres of agricultural land bounded to the east by North Sanderson Avenue. The adjoining properties to the north, south, and west, as well as east beyond North Sanderson Avenue, are mainly agricultural and/or fallow land. No mailing addresses are currently assigned to the Site. The Site has been primarily developed for agricultural purposes (row crops and feed crops) since 1949. According to a representative of the Site owner, agricultural production at the Site has included watermelon and grain for animal feed. At the time of Roux's Phase II fieldwork, the Site was being used to grow corn. As discussed above, the extensive agricultural use of the Site and therefore, likely use of pesticides represents a REC. Typical pesticide uses during this time period included the use of arsenic-based and lead-based pesticides (up until the 1960s) and organochlorine pesticides (OCPs, 1940s to 1970s).

At the time of the Roux's sampling event, the Site had been cleared with four evenly spaced aisles, each approximately 10 to 12 feet wide. Due to the presence of corn crops in the remaining areas of the Site, sample collection in a grid formation was not feasible. However, because application of pesticides is expected to have been to be uniform across the Site, the samples collected and data generated during this investigation are considered representative of the entire Site.

METHODS OF INVESTIGATION

The following sections summarize the investigation methods used during soil sampling events, including pre-field activities, sampling locations and procedures, and field observations.

5150 East Pacific Coast Highway, Suite 450 ■ Long Beach, California 90804 ■ +1.310.879.4900 ■ www.rouxinc.com
California ■ Illinois ■ Massachusetts ■ New Jersey ■ New York ■ Texas ■ Virginia

Pre-Field Activities

Prior to the start of field activities, Roux prepared a Site-specific Health and Safety Plan (HASP) to ensure worker safety. In addition to containing information regarding Roux's standard safety practices, the HASP contained information about potential hazards related to Site activities and provided the locations and contact information of nearby emergency services. Field workers acknowledged their familiarity with all safety procedures and indicated their intent to follow the HASP by signing the HASP after the tailgate safety meeting, which took place at the beginning of each field day. All personnel working in the exclusion zone were Occupational Safety and Health Administration (OSHA) trained, consistent with federal regulation 29 CFR 1910.120. At least 48 hours prior to fieldwork, the Site boundary was marked in white paint and Underground Service Alert (USA) of Southern California was notified of the intended work (USA Ticket Number B232820188). USA notified companies and agencies that may have underground utilities in the vicinity to mark their respective utilities on the ground with spray paint so that they were avoided during drilling.

Shallow Soil Sampling

On October 13, 2023, a total of 28 soil samples were collected from 12 quadrants (Figure 2). In addition, one randomly selected discrete soil sample (14 total) was collected from each quadrant (SS-1 through SS-12), including two duplicates (SS-Q1-DUP and SS-Q9-DUP). Four samples were collected with a trowel from each quadrant and composited in the field into a laboratory-provided glass jar. Twelve (12) composite samples (SS-COMP-1 through SS-COMP-12) were collected from the 12 quadrants with two duplicate composite samples (SS-COMP-4-DUP and SS-COMP-12-DUP).

All soil samples were collected across the Site at a depth of 0.5 feet below ground surface (bgs) as shown in Figure 2. Sampling equipment was cleaned in a solution of laboratory-grade detergent and rinsed with distilled water prior to sample collection at each quadrant location.

Composite and discrete soil samples were labeled with unique sample identifiers, placed on ice, and transported under proper chain-of-custody procedures to Enthalpy Analytical (Enthalpy) of Orange, California, a California-certified laboratory, for analysis. A total of 14 composite soil samples (12 primary and 2 duplicate) were analyzed for organochlorine pesticides (OCPs) by USEPA Method 8081A. A total of 14 discrete soil samples were analyzed for lead and arsenic by USEPA Method 6010B.

RESULTS

Analytical results were compared to the United States Environmental Protection Agency (USEPA) Regional Screening Levels (RSLs) and/or Department of Toxic Substances Control (DTSC) Human and Ecological Risk Office (HERO) Human Health Risk Assessment (HHRA) Note Number 3 DTSC-modified Screening Levels (DTSC SLs) for commercial/industrial soil. In addition, total lead and arsenic concentrations were compared with regional background levels, as presented in *Background Concentrations of Trace and Major Elements in California Soils*[1] and *Determination of a Southern California Regional Background Arsenic Concentration in Soil*[2]. Summaries of analytical results are provided in Tables 1 and 2. The analytical laboratory report is provided in Appendix A.

Organochlorine Pesticides in Soil

No OCP constituents were reported at concentrations above their respective laboratory method reporting limits (MRLs), as presented in Table 1. All MRLs were below applicable USEPA RSLs and DTSC SLs.

---

[1] Bradford, G. R., Change, A. C., Page, A. L., Bakhtar, D., Frampton, J. A., and Wright, H. Background Concentrations of Trace and Major Elements in California Soils. March 1996.
[2] Chernoff, G., Bosan, W., and Oudiz, D. and DTSC, Determination of a Southern California Regional Background Arsenic Concentration in Soil. March 2008.

Arsenic in Soil

Arsenic was detected above the laboratory reporting limit in 11 of the 12 samples at concentrations ranging from 1.5 to 2.9 milligrams per kilogram (mg/kg). Arsenic was detected above the DTSC SL of 0.36 mg/kg for commercial/industrial soil; however, detections of arsenic did not exceed the regional background concentration of 12 mg/kg in any sample (Table 2). Detections of arsenic did not exceed the USEPA RSL of 3.0 mg/kg for commercial/industrial soil.

Lead in Soil

Lead was detected above the laboratory reporting limit in all 12 samples at concentrations ranging from 3.8 to 9.9 mg/kg, well below the DTSC SL for commercial/industrial soil of 500 mg/kg and USEPA RSL for commercial/industrial soil of 800 mg/kg (Table 2).

CONCLUSIONS

The results of the Phase II Subsurface Investigation indicate that shallow soil OCP and select metals concentrations are below conservative regulatory thresholds for commercial/industrial land use and/or regional background concentrations. The REC identified in the Phase I ESA has been addressed and no further investigation is recommended at this time.

CLOSING

Should you have any questions or require any further information regarding the contents of this Report, please do not hesitate to contact Rocio Quinones by telephone at 562-446-8638 or by email at rquinones@rouxinc.com or Mauricio Escobar by telephone at 310-879-4920 or by email at mescobar@rouxinc.com.

Sincerely,

ROUX ASSOCIATES, INC.

Rocio Quinones
Project Scientist

Mauricio Escobar, P.G. - CA
Principal Geologist

Notes:
OCPs = organochlorine pesticides
USEPA = United States Environmental Protection Agency
USEPA RSL = USEPA Regional Screening Levels for Soil, Hazard Quotient (HQ) = 1.0, May 2023.
DTSC SL = Human Health Risk Assessment (HHRA) Note 3, Department of Toxic Substances Control Screening Levels (DTSC-SLs) for Soil, revised May 2022.
µg/Kg = microgram per kilogram
bgs = below ground surface
NS = No standard established
Italics indicates duplicate sample
<X = analyte not detected above laboratory RDL

SAMPLE ACCEPTANCE CHECKLIST

Section 1

Client: Rax Project: Shea San Jacinto

Date Received: 10/16/23 Sampler's Name Present: ☒ Yes ☐ No

Section 2

Sample(s) received in a cooler? ☒ Yes, How many? 1 ☐ No (skip section 2) Sample Temp (°C) (No Cooler): _____

Sample Temp (°C), One from each coole #1: 3.9 #2: _____ #3: _____ #4: _____

(Acceptance ronge is < 6°C but not frozen (for Microbiology samples, occeptance ronge is < 10°C but not frozen). It is occeptable for samples collected the same day as somple receipt to hove a higher temperature as long as there is evidence that cooling has begun.)

Shipping Information: _____

Section 3

Was the cooler packed with: ☒ Ice ☐ Ice Packs ☐ Bubble Wrap ☐ Styrofoam ☐ Paper ☐ None ☐ Other _____

Cooler Temp (°C): #1: 0-7 #2: _____ #3: _____ #4: _____

Section 4	YES	NO	N/A
Was a COC received?	X		
Are sample IDs present?	X		
Are sampling dates & times present?	X		
Is a relinquished signature present?	X		
Are the tests required clearly indicated on the COC?	X		
Are custody seals present?		X	
If custody seals are present, were they intact?			X
Are all samples sealed in plastic bags? (Recommended for Microbiology samples)			X
Did all samples arrive intact? If no, indicate in Section 4 below.	X		
Did all bottle labels agree with COC? (ID, dates and times)	X		
Were the samples collected in the correct containers for the required tests?	X		
Are the containers labeled with the correct preservatives?			X
Is there headspace in the VOA vials greater than 5-6 mm in diameter?			X
Was a sufficient amount of sample submitted for the requested tests?	X		

Section 5 Explanations/Comments

_____

_____

_____

Section 6

For discrepancies, how was the Project Manager notified? ☒ Verbal PM Initials: _____ ☐ Email (email sent to/on): _____

Project Manager's response:

_____

_____

Completed By: _____ Date: 10/16/23

UST CASE NO. 083303601T

Dear Mr. Westra:

This letter confirms the completion of the site investigation and remedial action for the underground storage tanks formerly located at the above-described location. Enclosed is the Case Summary for the referenced site for your records.

Based upon the available information, including current land use, and with the provision that the information provided to this agency was accurate and representative of site conditions, no further action that is related to the underground storage tank removal is required.

This notice is issued pursuant to a regulation contained in Title 23, California Code of Regulations, Division 3, Chapter 16, Section 2721(e).

Please provide documentation of well abandonment to this office to complete our file. Please contact Rose Scott of our office at (909) 320-6375, if you have any questions regarding this matter.

Sincerely,

for Gerard J. Thibeault
Executive Officer

Enclosure: Case Closure Summary

Monitoring or vapor wells decommissioned: YES [ ] NO [x] N/A [ ]
Number decommissioned: none

List of enforcement actions taken: none
List enforcement action rescinded: none

VII. ADDITIONAL COMMENTS, DATA, ETC.

On December 14, 1999, three gaolsine underground storage tanks (USTs) were removed from the site under the direction of Riverside County. The tank area was over-excavated by Consolidated Waste Industries, and the contaminated soil (approximately 120 tons) was transported to TPS recycling in Adelanto, California. The highest concentrations of petroleum hydrocarbons detected beneath the gasoline tanks are shown on the preceding table. These are the concentrations left in place at the bottom of the excavation. On March 15, 2000, the County of Riverside Health Services Agency Department of Environmental Health transferred this case to our office for Regional Board oversight for jurisdictional reasons.

In October 2000, three borings were drilled at the site to depths of 60 to 70 feet below ground surface (bgs). Groundwater was not detected to a depth of 70 feet below ground surface. The expected depth to groundwater is reported to be 120 feet or greater. The site is underlain by sandy silt, silty sand and gravelly sand. The highest concentrations of petroleum hydrocarbons were detected in the 15-foot sample from Boring S-1. In addition to the contaminants identified in the table above, the following compounds were

detected: Naphthalene at 32.3 mg/kg, N-propylbenzene at 34.6 mg/kg, 1,2,4-trimethylbenzene at 248.0 mg/kg, 1,3,5-trimethylbenzene at 82.8 mg/kg, and 2-Methylnaphthalene at 33.6 mg/kg. The concentrations significantly decreased with depth indicating that the extent of petroleum hydrocarbons was limited to between 15 and 20 feet bgs. In the soil samples collected at 25, 35 and 60 feet bgs, TPH, MTBE, toluene, ethylbenzene and xylenes were detected at low concentrations (less than 0.5 mg/kg). Petroleum hydrocarbons were not detected in boring S-2 and were only detected at low concentrations (0.147 mg/kg TPH, 0.009 mg/kg benzene, 0.031 mg/kg toluene, 0.012 mg/kg xylenes and 0.186 mg/kg MTBE) in the 15 and 20-foot samples from boring S-3, indicating that the lateral extent of petroleum hydrocarbons in soil was also limited.

In December 2000, Regional Board staff recommended an extended vapor extraction test in order to evaluate the mass of petroleum hydrocarbons in the soil available for vapor recovery. On May 7, 2001, one vapor extraction well was installed in the area of the highest concentrations of petroleum hydrocarbons in soil and a 7-hour vapor extraction test was conducted. Vapor samples were collected at the beginning, middle and end of the test. The highest concentrations were detected at the mid-point of the test. The influent concentrations of TPH and MTBE decreased from the beginning to the end of the test from 3,000 and 400 ppmv to 2,300 and 270 ppmv, respectively. Concentrations of benzene increased from 0.14 ppmv at the beginning of the test to 27 ppmv at the middle and 0.17 ppmv at the end. MTBE also increased slightly during the mid-test sampling. At a flow rate of 30 scfm, only 9.55 pounds of hydrocarbons were removed during the test. The results of the test indicated that there is not a significant source of petroleum hydrocarbons remaining in the soil that would pose a threat to groundwater resources.

No further action is recommended for the following reasons:

- The areas primarily affected by the release were remediated by excavation and off-site disposal of approximately 120 tons of soil containing petroleum hydrocarbons.
- Assessment results indicated the residual petroleum hydrocarbons in soil are limited to an area estimated to have a 15-foot radius between 15 and 20 feet bgs, southeast of the maintenance building.
- Concentrations in extracted vapors during the vapor extraction test did not indicate a significantly rich source of petroleum hydrocarbons in soil.
- Groundwater is expected to be at a depth of 120 feet, at least 60 feet below the deepest detected compound (MTBE at a concentration of 0.089 mg/kg of MtBE, using EPA Method 8021) and 100 feet beneath the deepest detected benzene (0.006 mg/kg).

Dear Mr. Gerard J Thibeault:

In response to your letter dated December 26,2001 the study well at the above location has been properly sealed and abandoned. Please use this letter as our confirmation of the completion of the site investigation and remedial action.

No further action is necessary.

We thank you as a family for all your work in the above mentioned case.

Sincerely,

Cal Westra

Vice President | Principal Geologist

EXPERIENCE SUMMARY

21 years of consulting experience: Principal Geologist with Roux Associates (2011 to Present); Senior Manager, Manager, and Senior Associate with ENVIRON International Corporation (2004 to 2011); Project Geologist with URS Corporation (2001 to 2004); Geologist with Hart Crowser (1998 to 2001).

TECHNICAL SPECIALTIES

Professional Geologist with over twenty years of experience designing, managing, and implementing environmental soil and groundwater investigations and remediation strategies for public and private clients. Experience as in-house consultant assisting with management of a $25MM yearly remediation portfolio for a Fortune 100 Company. Practice developing and implementing high-level strategies that consider legal and regulatory issues, communications and government relations, as well as technical challenges and costs. Significant assignments representing clients during Working Group meetings for Superfund sites and participation in technical committee meetings. Expertise in design and field implementation of in-situ chemical oxidation (ISCO) in hard rock and porous media-flow aquifers.

Substantial experience evaluating and remediating industrial, commercial and residential sites impacted with numerous contaminants in multiple media, including crude oil, fuels, volatile organic compounds, chromium VI, 1,4-dioxane, and PCBs. Extensive experience managing implementation of remediation programs that utilize and consider multiple technologies including soil vapor extraction, dual phase extraction, traditional pump and treat, in-well stripping, air sparging, chemical oxidation and reduction, thermal treatment, and natural attenuation. Experience managing large-scale remedial excavations involving the use of heavy earth moving equipment. Significant field experience using numerous drilling, soil sampling, groundwater sampling, and soil vapor sampling techniques.

CONTINUING EDUCATION

- Compounds of Emerging Concern in Groundwater, California Groundwater Resources Association, Concord, California, February 2012
- The Remediation Course, Princeton Groundwater, Las Vegas, Nevada, April 2010
- Vapor Intrusion Pathway: A Practical Guideline, Interstate Technology and Regulatory Council (ITRC) in conjunction with the California Department of Toxic Substances (DTSC) and California Water Boards, Long Beach, California, June 2009
- The Groundwater Pollution and Hydrology Course, Princeton Groundwater, Orlando, Florida, February 2007
- Hydrogeologic Analysis of Fractured Bedrock Systems, Midwest GeoSciences Group, University of Nevada Las Vegas and Nevada Test Site at Yucca Mountain, March 2006

REPRESENTATIVE PROJECTS

- **PRP Representation of Fortune 100 Company, Omega Chemical Superfund Site, Whittier, California.** Provide ongoing technical consulting to a Fortune 100 Company and major PRP at the Omega Chemical Superfund Site in Whittier, California. Active participant of the Omega PRP Group (OPOG) Technical Committee. Attend all pertinent technical meetings and provide Client with technical and strategic input that protects their best interests. Maintain constant interaction with the legal and finance teams as necessary to ensure the technical and legal strategies are in agreement and that adequate funding is reserved well in advance of regulatory commitments and OPOG cash calls. Pertinent technical issues include soil gas and vapor intrusion, and a regional groundwater plume. Regulatory oversight is provided by USEPA Region IX.

- **PRP Representation of Fortune 100 Company, BKK Corporation Class I Landfill Organized Group, West Covina, California.** Provide ongoing technical consulting to a Fortune 100 Company at the former BKK Corporation Class I Landfill site in West Covina, California. Participant in the BKK Technical Committee and attendant of pertinent technical meetings. Maintain constant communication with the Client's legal and finance teams and responsible for informing Client on the direction the Organized Group is headed. Responsible for identifying financial commitments made as part of technical decisions. Trusted with voicing opinions, concerns, and/or offering direction to the Group (if and when necessary), to ensure the Organized Group's direction is consistent with the Client's strategy. Pertinent technical issues include upgrades to the landfill infrastructure and groundwater remedial investigations in and around the landfill prism. Regulatory oversight is provided by the Department of Toxic Substances Control.
- **Portfolio Project Control - Fortune 100 Company, Torrance, California.** Three years of experience working as a full-time in-house consultant for a Fortune 100 Company assisting with management of all aspects of a complex multi-site portfolio. General role included communication with alliance partners, vendors, corporate finance, attorneys, public relations/communications, and procurement to track and facilitate progress of 9 major projects ($400,000 to $1 MM/year) and 3 mega projects ($3MM to $10MM+/year) that were unique in nature and complexity. Portfolio included former chemical sites, landfills, aerospace facilities, and other heavy use industrial facilities that were undergoing State and RCRA closure, as well as sites under CERCLA Superfund actions with PRP commitments. Charged with helping to develop, evaluate, and refine remedial strategies and lifecycle costs for sites that utilized various cleanup technologies such as application of oxidants and reducing agents, thermal oxidation, groundwater pump and treat, dual-phase and 2-PHASE™ extraction, soil vapor extraction, air sparging, and in-well air stripping. Major role included verifying adequate funding and maintaining documentation consistent with Sarbanes Oxley.
- **Strategy Expert Consulting - Fortune 100 Company, Los Angeles, California.** Ongoing third-party technical and strategic support to a Fortune 100 company for a major project involving former bulk storage and distribution facilities converted to open public space and residential uses. Site is undergoing remedial investigations and remedial alternatives evaluations under heavy regulatory and public scrutiny. Charged with providing opinions and recommendations as to the direction the current consultant and the regulatory agencies want to take the project and evaluating the conceptual site model and long term technical strategy. Active participant on technical team calls and ongoing direct communications with internal legal team.
- **Shipyard Decommissioning - Subsurface Assessment, Remedial Investigation, Demolition and Closure, Campbell Shipyard - Marco, Port of San Diego, California.** Lead geologist in the preparation of a comprehensive subsurface study of the former Campbell Shipyard property at the Port of San Diego, California. Over 200 borings were necessary to delineate the extent of impacted soils. Relevant environmental issues included a former coal works gasification plant immediately adjacent to the Site, a 2 to 4-foot thick lens of polynuclear aromatic hydrocarbon (PAH) laden sediment present throughout the Site below the water table, a former on-site diesel and kerosene tank farm, and numerous leaking fuel USTs. Responsibilities also included management of shipyard abandonment activities, such as abatement of asbestos and lead-based paint containing materials, demolition of on-site structures, crushing of asphalt and concrete into Class II base, and a comprehensive geophysical survey to locate all on-site utilities and buried structures. The work was performed under the regulatory oversight of the San Diego Regional Water Quality Control Board and the San Diego Unified Port District. Total cost of the work was approximately $1.3MM, implemented over a 15-month period.
- **Neutral Third-Party Oversight of Remediation Work, ITT Corporation and Home Depot, Glendale, California.** Provided third party oversight for a site undergoing major remediation of VOCs and chromium VI in soils and groundwater. The site was a former electronics manufacturing facility redeveloped as a major box retailer in Glendale, California. Services were provided on behalf of the former facility owners/operators and the current property owners, both of whom had differing interests and views on the remedial work being performed. Viewed all fieldwork and construction of remediation systems and attended quarterly meetings with consultants, attorneys, and clients to gauge progress, discuss ongoing work, and evaluate projected schedules for completion of remediation. Technical challenges to remediation included dewatering of 20-foot thick perched zone impacted with VOC contamination, despite a leaking slurry wall originally designed to prevent onsite migration from upgradient sources.
- **ISCO Demonstration Plan Using Permanganate, Wyle Laboratories, Riverside County, California.** Designed, managed, and implemented an ISCO Demonstration Plan using sodium permanganate injection at a former industrial manufacturing facility in Southern California. Main goals of the application were to demonstrate effective oxidation of trichloroethene (TCE) in alluvium and fractured granitic bedrock, evaluate potential mobilization of naturally occurring reduced metals, and evaluate the potential application of ISCO

at other areas of the Site, including off-site beneath residential homes. Twelve thousand gallons of 10% permanganate solution were delivered to the subsurface through 47 multi-depth permanent injection probes over a 22-day field event. TCE concentrations were reduced from a maximum of 30,000 microgram per liter (µg/L) to non-detect at the source area. Significantly, elevated hexavalent chromium [Cr(VI)] concentrations were observed in the area of injection and immediately downgradient. Following field observations, a Bench Scale Assessment (BSA) was conducted to evaluate potential significant sources of Cr(VI), evaluate the capacity of the aquifer to naturally attenuate Cr(VI), and provide data sufficient to estimate distance and time Cr(VI) would revert to its trivalent form. BSA and field data showed that principal source of Cr(VI) was from the raw product, with secondary contribution from chromium in the native rock, and deterioration of stainless steel well screens. Natural attenuation of Cr(VI) to background concentrations was estimated at 2 to 3 years post injection. Monitoring of the Demonstration Plan area for the 2+ years has proved those predictions accurate and a Remedial Action Plan (RAP) recommending full-scale on- and off-site treatment of TCE with permanganate was submitted to the California Department of Toxic Substances Control (DTSC). Total cost of the work was more than $1.0 million.

- **Remedial Excavation and ISCO Used to Facilitate Property Transfer, Sanmina, Inc., Irvine, California.** Managed and implemented an aggressive remedial strategy for a former electronics manufacturing facility in Southern California. The site had TCE concentrations in groundwater suggestive of dense non-aqueous phase liquid (DNAPL) and required expedited soil and groundwater remediation, in lieu of ongoing 2-PHASE™ and dual-phase extraction (DPE) efforts, to accommodate its divesture and redevelopment. Groundwater was generally encountered at 15 feet below ground surface (bgs) and contained TCE concentrations in the source area as high as 77,000 µg/L. The project was successfully completed by installing a 90-well dewatering system, excavating 13,000 cubic yards (cy) of soils, and removing 3,200 cy of TCE impacted soil along the axis of a residual TCE DNAPL mass; total depth of the excavation was 32 feet bgs. ISCO using sodium and potassium permanganate was used to remediate residual TCE-impacted soil and groundwater outside the area of excavation. Following implementation of the aggressive remedial strategy, TCE concentrations in groundwater were reduced by one to three orders of magnitude, suggesting the DNAPL had been removed and/or destroyed. The Orange County Health Care Agency (OCHCA) provided soils closure and the Santa Ana Regional Water Quality Control Board provided groundwater closure for the site 16 months after completion of remediation. The site was sold and redeveloped. Total cost of excavation and ISCO application was approximately $1.4 million.

- **Assessment, Remediation and Closure of Former Industrial Facility for Residential Re-development, Former Boeing Plant, Los Angeles, California.** Managed the assessment, remediation, and closure of a former asphalt batch plant and defense contractor facility on behalf of a residential developer. The work was performed simultaneously with planning and entitlement of the property, under the oversight of the County of Los Angeles Fire Department, Hazardous Materials Division. Unique challenges included the discovery of 15+ feet of buried asphalt debris and soils with elevated arsenic and chromium concentrations requiring off-site disposal. Developed site-specific cleanup thresholds for VOCs and heavy metals by preparing a limited human health risk assessment and incorporating Risk Based Screening Levels (RBSLs) developed by the San Francisco Regional Water Quality Control Board. The entire project was implemented in 15 months from initial assessment to site closure at a cost of $250,000.

- **Hydrocarbon Release Characterization and Remedial Investigation, Kinder Morgan Energy Partners, La Habra, California.** Designed, managed, and implemented a subsurface investigation with the primary focus of characterizing lateral and vertical distribution of hydrocarbon impacts to the groundwater and unsaturated zone. The release was related to a pipeline booster station flange rupture dating to the early 1980s. Fractured siltstone bedrock presented unique subsurface conditions and as a result, special consideration was given to drilling techniques and boring/well installations. The project involved 12 months of fieldwork for the installation of soil vapor probes, backhoe trenches, soil borings, and monitoring wells. Discovery of up to 15-feet of light non-aqueous phase liquids (LNAPL) resulted in amendments to the original work scope to provide for LNAPL removal and assessment of pneumatic and hydraulic properties of the soil/rock. A high vacuum DPE test was performed at selected wells to evaluate the feasibility of this technology for the removal of hydrocarbons. All work was conducted under the oversight of the Los Angeles Regional Water Quality Control Board in consideration of future residential development. Work was performed over a 2-year period at an approximate cost of $1.0 million.

- **Resource Conservation and Recovery Act (RCRA) Facility Investigation Work Plan for Bunker C Tank Farm Redevelopment, Long Beach, California.** Managed the preparation of a RCRA Facility Investigation Work Plan for a former power plant tank farm facility in Long Beach, California. The site was being planned for redevelopment with a retail box store and restaurant uses. The RFI Work Plan was prepared as part of a Corrective Action Consent Agreement between the

Client and the DTSC. The purpose of the RFI was to determine the nature and extent of releases at the site and to gather all the necessary data to support completion and implementation of a Corrective Measures Study (CMS).

- **Remedial Investigation of Former Transformer Washing Facility, General Electric and City of Los Angeles Redevelopment Agency, Los Angeles, California.** Prepared, managed, and implemented a Remedial Investigation Work Plan for a former transformer washing facility under the oversight of the DTSC. The field investigation was intended to evaluate and delineate the nature and extent of residual VOC, PCB, and dioxin impacts at the Site, to support decisions regarding the need for, and extent of, future removal or remedial actions. The field program showed that shallow soils at the site were significantly impacted with PCBs and deep soils and groundwater were significantly impacted with TCE and tetrachloroethene (PCE). ISCO Demonstration Plan Using Permanganate, Riverside County, California.
- **Remedial Investigation and Remedial Action Plan for Former Small Arms Firing Range, City of Huntington Beach Community Development Office, Huntington Beach, California.** Managed the preparation of a Remedial Investigation and RAP for the City of Huntington Beach in their effort to assess the extent of contamination and remedial options for a former public and police firing range. The project was performed under the oversight of the OCHCA. Relevant issues included soil berms and coal-tar treated wood posts impregnated with lead-shot, shallow landfill conditions (<5-feet), lack of a landfill cap, heavy hydrocarbon contamination, and landfill gas issues. The RAP included remedial options, costing, and an outline for implementation. Special consideration was given to the fact that the City intended to use the property for future Central Park recreational uses. The project was awarded on technical merit following a public bidding process that required the submittal of a formal proposal and interviews with City officials. Total cost of the project was $150,000, implemented over a 2-year period.

OSHA 40-Hour HAZWOPER (2021)

Rocio Quiñones

Project Scientist

EXPERIENCE SUMMARY

More than eight years of cumulative environmental consulting experience. Began as a Due Diligence Project Manager with AEI Consultants in June 2013. Joined Roux' Long Beach office as a Project Scientist in December 2020.

TECHNICAL SPECIALTIES

Provide comprehensive phase I/II environmental site assessments and investigations examining potential impacts on soil, soil vapor, and groundwater. Other areas of focus include litigation support including historical research, agency file reviews, and report writing.

REPRESENTATIVE PROJECTS

ASTM E1527-13 Phase I ESAs

- Primary author of numerous Phase I ESAs conducting historical document review including agency files, aerial photographs, Sanborn fire insurance maps and site inspections for multiple sites in the greater Los Angeles basin. Compiled assessment observations in a Phase I report according to ASTM E1527-13 standard.
- Sites with Phase I ESA experience include current and historical industrial facilities, current oil production facility, school sites, agricultural sites, and multi-tenant commercial properties.
- Project Scientist for an inactive steel mill in San Bernardino County, California. Performed site walk, interviews with key personnel, reviewed regulatory agency records including remediation reports, and identified data gaps in previous investigations.
- Project Scientist for former chemical manufacturing facility in Northern California. Site under oversight of the Department of Toxic Substances Control (DTSC) for releases of volatile organic compounds to soil, soil vapor, and groundwater. Reviewed previous investigation and remediation reports and assisted in writing a workplan for proposed remediation.
- Project Scientist for current manufacturing facility / former plating facility located within a regional groundwater plume in Orange County, California. Reviewed regional groundwater reports and prepared a site investigation workplan to investigate potential on-site impacts to soil, soil vapor, and groundwater.

Site Investigation and Remediation

- Planned, oversaw, and managed several Phase II Environmental Site Assessments. Conducted field investigations, completed data analyses, preparation of reports for submittal to regulatory agencies, and the provision of recommendations for remediation.
- Experience includes Phase II subsurface investigations, soil sampling, and soil vapor sampling. Site types include automotive repair and former manufacturing facilities.
- Coordinate agency permitting and regulations, multiple subcontractors (geophysical, driller, laboratories, etc..), site personnel, and internal and client communication to ensure projects progress smoothly and any obstacles or delays are minimized and conveyed to clients as early as possible.
- Project Scientist for a soil investigation at an active large-scale printing facility in Orange County, California. Field work included coring, hand augering, and collection of soil samples to quantify potential impacts due to historical operations as part of property transaction due diligence.

Re: Phase II Subsurface Investigation Letter Report, Line E (Proposed Irrigation Channel), North Sanderson Avenue and Record Road, San Jacinto, Riverside County, California

Dear Mr. Perales:

Roux Associates, Inc. (Roux) has prepared this Phase II Subsurface Investigation Letter Report (Phase II Report) for Shea Properties (Client), to summarize the findings of shallow soil sampling conducted along portions of Line E (Proposed Irrigation Channel), North Sanderson Avenue, and Record Road in the City of San Jacinto, Riverside County, California (Site; Figure 1). Roux completed a Phase I Environmental Site Assessment (ESA), dated January 30, 2024, which identified a recognized environmental concern (REC) associated with potential impacts from agricultural chemicals to on-Site soils within Parcels 3, 4, 5, and 9 from agricultural operations (row crops). To address the identified environmental concern, Roux collected composite and discrete soil samples from eleven locations (quadrants) across the Site to establish baseline conditions and identify potential impacts in the shallow soil associated with historical agricultural use. Soil sampling was conducted in general accordance with the California Department of Toxic Substances Control (DTSC) *Interim Guidance for Sampling Agricultural Properties*, dated August 7, 2008.

BACKGROUND

The Site consists of a proposed irrigation channel alignment and traverses nine individual parcels (collectively identified as the Parent Property) identified by Riverside County Assessor's Parcel Numbers (APNs) 436-170-008, 436-170-016, 436-170-001, 436-030-004, 436-010-003, 432-030-012, 432-030-010, 432-030-006, and 430-100-018 (Parcels 1 through 9). According to Site representatives, agricultural production at the Site has included watermelon, corn, and grain for animal feed. At the time of Roux's Phase II fieldwork, the Site was fallow agricultural land.

According to historical aerial photographs, agricultural operations (row crops) have been conducted on Subject Property areas within Parcels 3, 4, 5, 6, 7, and 8 since at least 1949. Previous site investigations conducted within Parcels 6, 7, and 8 did not identify significant evidence of soil contamination associated with historical crop growth. Parcel 9 appeared developed for agricultural use circa 1975 and again in 2023. The potential for impacts from agricultural chemicals to on-site soils within Parcels 3, 4, 5, and 9 was identified in Roux's Phase I ESA as a REC. Typical pesticide uses during this time period included the use of arsenic-based and lead-based pesticides (up until the 1960s) and organochlorine pesticides (OCPs, 1940s to 1970s).

METHODS OF INVESTIGATION

The following sections summarize the investigation methods used during soil sampling events, including pre-field activities, sampling locations and procedures, and field observations.

5150 East Pacific Coast Highway, Suite 450 ■ Long Beach, California 90804 ■ +1.310.879.4900 ■ www.rouxinc.com
California ■ Illinois ■ Massachusetts ■ New Jersey ■ New York ■ Texas ■ Virginia

Pre-Field Activities

Prior to the start of field activities, Roux prepared a Site-specific Health and Safety Plan (HASP) to ensure worker safety. In addition to containing information regarding Roux's standard safety practices, the HASP contained information about potential hazards related to Site activities and provided the locations and contact information of nearby emergency services. Field workers acknowledged their familiarity with all safety procedures and indicated their intent to follow the HASP by signing the HASP after the tailgate safety meeting, which took place at the beginning of each field day. All personnel working in the exclusion zone were Occupational Safety and Health Administration (OSHA) trained, consistent with federal regulation 29 CFR 1910.120. At least 48 hours prior to fieldwork, the Site boundary was marked in white paint and Underground Service Alert (USA) of Southern California was notified of the intended work (USA Ticket Numbers A240431099-00A and A240431109-00A). USA notified companies and agencies that may have underground utilities in the vicinity to mark their respective utilities on the ground with spray paint so that they were avoided during drilling.

Shallow Soil Sampling

Between February 15 and February 16, 2024, a total of 54 soil samples were collected from eleven quadrants (Figures 2 and 3). Four samples were collected with a trowel from each quadrant and composited in the field into a laboratory-provided glass jar, for a total of thirteen (13) composite samples (P9-Q1 through P3-Q11), including two duplicate composite samples (P9-Q2-DUP and P4-Q6-DUP). In addition, one randomly selected discrete soil sample was collected from each quadrant in parcels 3, 4, and 5 (eight total) (P5-P5-1 through P3-Q11-1), including one duplicate sample (P4-Q7-1-DUP).

All soil samples were collected across the Site at a depth of 0.5 feet below ground surface (bgs), as shown in Figures 2 and 3. Sampling equipment was cleaned in a solution of laboratory-grade detergent and rinsed with distilled water prior to sample collection at each quadrant location.

Composite and discrete soil samples were labeled with unique sample identifiers, placed on ice, and transported under proper chain-of-custody procedures to Enthalpy Analytical (Enthalpy) of Orange, California, a California-certified laboratory, for analysis. A total of 13 composite soil samples (11 primary and 2 duplicate) were analyzed for organochlorine pesticides (OCPs) by USEPA Method 8081A. A total of 8 discrete soil samples (7 primary and 1 duplicate) were analyzed for lead and arsenic by USEPA Method 6010B.

RESULTS

Analytical results were compared to the United States Environmental Protection Agency (USEPA) Regional Screening Levels (RSLs) and/or Department of Toxic Substances Control (DTSC) Human and Ecological Risk Office (HERO) Human Health Risk Assessment (HHRA) Note Number 3 DTSC-modified Screening Levels (DTSC SLs) for commercial/industrial soil. In addition, total lead and arsenic concentrations were compared with regional background levels, as presented in *Background Concentrations of Trace and Major Elements in California Soils*[1] and *Determination of a Southern California Regional Background Arsenic Concentration in Soil*[2]. Summaries of analytical results are provided in Tables 1 and 2. The analytical laboratory report is provided in Appendix A.

[1] Bradford, G. R., Change, A. C., Page, A. L., Bakhtar, D., Frampton, J. A., and Wright, H. Background Concentrations of Trace and Major Elements in California Soils. March 1996.
[2] Chernoff, G., Bosan, W., and Oudiz, D. and DTSC, Determination of a Southern California Regional Background Arsenic Concentration in Soil. March 2008.

Organochlorine Pesticides in Soil

No OCP constituents were reported at concentrations above their respective laboratory method reporting limits (MRLs), as presented in Table 1. All MRLs were below applicable USEPA RSLs and DTSC SLs.

Arsenic in Soil

Arsenic was detected above the laboratory reporting limit in all eight samples at concentrations ranging from 1.0 to 1.4 milligrams per kilogram (mg/kg). Arsenic was detected above the DTSC SL of 0.36 mg/kg for commercial/industrial soil; however, detections of arsenic did not exceed the regional background concentration of 12 mg/kg in any sample (Table 2). Detections of arsenic did not exceed the USEPA RSL of 3.0 mg/kg for commercial/industrial soil.

Lead in Soil

Lead was detected above the laboratory reporting limit in all eight samples at concentrations ranging from 1.8 to 2.4 mg/kg, well below the DTSC SL for commercial/industrial soil of 500 mg/kg and USEPA RSL for commercial/industrial soil of 800 mg/kg (Table 2).

CONCLUSIONS

The results of the Phase II Subsurface Investigation indicate that shallow soil OCP and select metals concentrations are below conservative regulatory thresholds for commercial/industrial land use and/or regional background concentrations. The REC identified in the Phase I ESA has been addressed and no further investigation is recommended at this time.

CLOSING

Should you have any questions or require any further information regarding the contents of this Report, please do not hesitate to contact Mauricio Escobar by telephone at 310-480-2561 or by email at mescobar@rouxinc.com.

Sincerely,

ROUX ASSOCIATES, INC.

Mauricio H. Escobar, P.G. - CA
Principal Geologist

SAMPLE ACCEPTANCE CHECKLIST

Section 1

Client: Rouy

Project: Shea Irrigation

Date Received: 2/16/24

Sampler's Name Present: ☑ Yes ☐ No

Section 2

Sample(s) received in a cooler? ☑ Yes, How many? 1 ☐ No (skip section 2)

Sample Temp (°C) (No Cooler): _____

Sample Temp (°C), One from each cooler: #1: 2.5 #2: _____ #3: _____ #4: _____

(Acceptance range is < 6°C but not frozen (for Microbiology samples, acceptance range is < 10°C but not frozen). It is acceptable for samples collected the same day as sample receipt to have a higher temperature as long as there is evidence that cooling has begun.)

Shipping Information: _____

Section 3

Was the cooler packed with: ☑ Ice ☐ Ice Packs ☐ Bubble Wrap ☐ Styrofoam ☐ Paper ☐ None ☐ Other _____

Cooler Temp (°C): #1: 1.6 #2: _____ #3: _____ #4: _____

Section 4	YES	NO	N/A
Was a COC received?	✓		
Are sample IDs present?	✓		
Are sampling dates & times present?	✓		
Is a relinquished signature present?	✓		
Are the tests required clearly indicated on the COC?	✓		
Are custody seals present?		✓	
If custody seals are present, were they intact?			✓
Are all samples sealed in plastic bags? (Recommended for Microbiology samples)			✓
Did all samples arrive intact? If no, indicate in Section 4 below.	✓		
Did all bottle labels agree with COC? (ID, dates and times)	✓		
Were the samples collected in the correct containers for the required tests?	✓		
Are the containers labeled with the correct preservatives?			✓
Is there headspace in the VOA vials greater than 5-6 mm in diameter?			✓
Was a sufficient amount of sample submitted for the requested tests?	✓		

Section 5 Explanations/Comments

Section 6

For discrepancies, how was the Project Manager notified? ☐ Verbal PM Initials: _____ Date/Time _____

☐ Email (email sent to/on): _____ / _____

Project Manager's response:

Completed By: _____ Date: 2/16/24

Section 1 Background

The Master Drainage Plan (MDP) for the San Jacinto Valley was adopted in October 2015 by the Board of Supervisors for the Riverside County Flood Control & Water Conservation District (RCFC&WCD). The MDP encompasses portions of the cities of San Jacinto and Hemet as well as parts of unincorporated Riverside County. The MDP is bounded by the San Jacinto River to the north, Florida Avenue to the south, Meridian Street to the east, and Warren Road to the west as shown in ***Figure 1***.

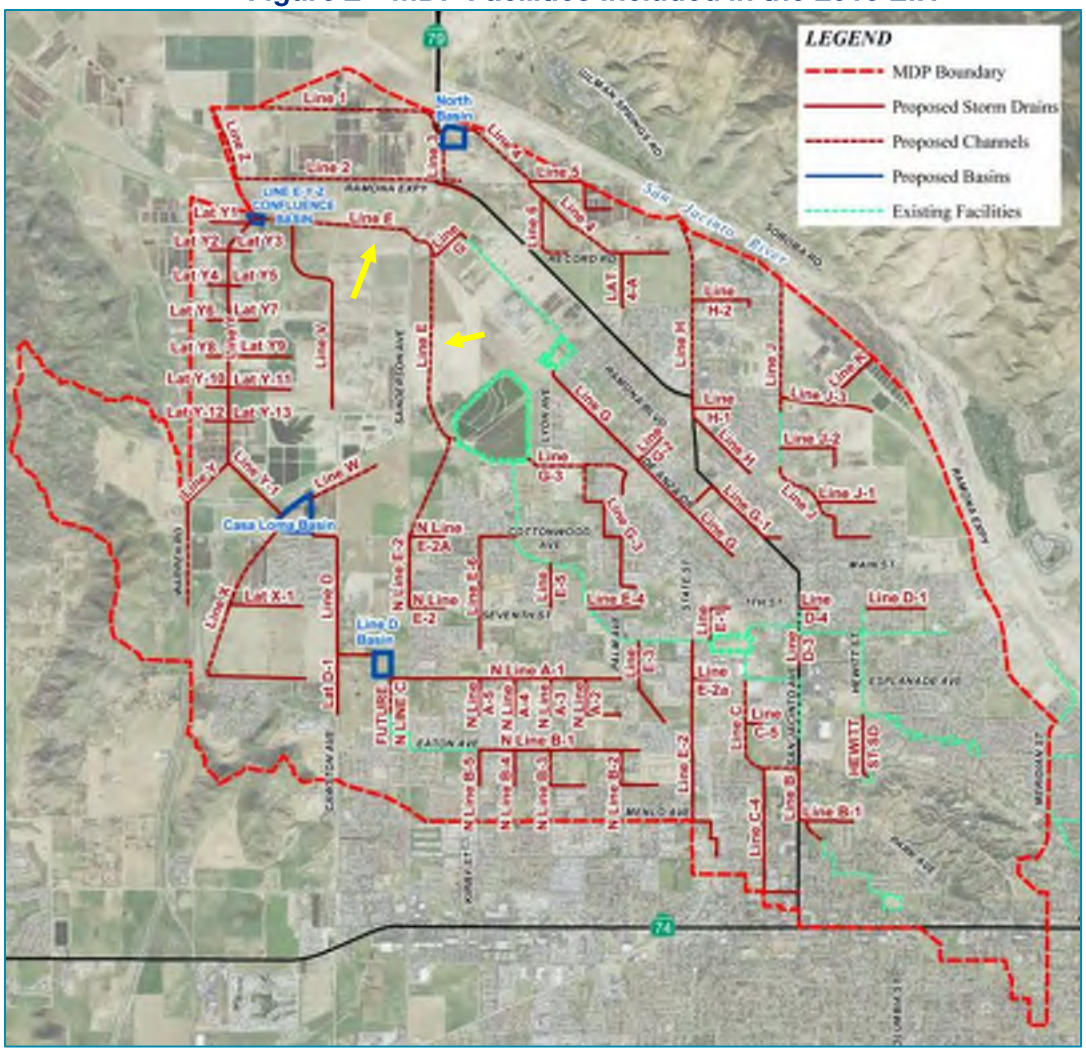

Figure 1 – Boundary of San Jacinto Valley Master Drainage Plan

Master Drainage Plans, by their very nature, are living documents. They provide a baseline strategy that can be modified as areas build out. Such is the case with the San Jacinto Valley MDP.

An Environmental Impact Report (EIR) for the San Jacinto Valley MDP and the San Jacinto Regional Area Drainage Plan (ADP) Amendment was certified by the San Jacinto City Council on January 14, 2013 (WEBB(a)). The certified EIR analyzed the MDP facilities shown in ***Figure 2*** (State Clearinghouse No. 2009041077). Note the yellow arrows in ***Figure 2*** pointing out Line E.

Figure 2 – MDP Facilities Included in the 2013 EIR

San Jacinto Master Developer, LLC (SJMD, LLC) submitted a development application to the City of San Jacinto for the proposed "San Jacinto Commerce Center Specific Plan" (SJCCSP or Specific Plan), which is located within the San Jacinto Valley MDP and a portion of the tributary area of Line E (***Figure 3***). Line E is a planned regional drainage facility that would provide a service to an approximately 1,870-acre tributary area that includes the 510-acre SJCCSP parcels in addition to many other property owners. As a major stakeholder relying on proper drainage of the area, SJMD, LLC will lead the planning, design, and construction of Line E on behalf of the City of San Jacinto.

SJMD, LLC retained the services of Albert A. Webb Associates (WEBB) to prepare the long-axis plan and this Preliminary Design Report (PDR) for the construction of Line E. The long-axis plan is located in **Appendix A.** RCFC&WCD will review this PDR and long-axis plan in order for SJMD, LLC to construct said facilities. This PDR is based on a 30% long-axis plan. Upon completion of CEQA and approval of this PDR for Line E, final engineering will commence.

Figure 3– Tributary Area of Proposed Line E Project

1.1 Scope of Work

To design the backbone MDP components to flood-protect the proposed SJCCSP, WEBB undertook the following scope of work:

1. Review existing MDP Line E flows and alignment;
2. Determine project design constraints with additional potholing, and topographic data;
3. Develop the proposed alignment considering design constraints and stakeholder input;
4. Obtain geotechnical and structural engineering design support;
5. Update MDP hydrology based on proposed layout;
6. Build hydraulic model of proposed alignment and updated flow rates;
7. Develop long-axis plan and kickoff environmental studies; and
8. Document results in PDR report.

1.2 Stakeholder Involvement

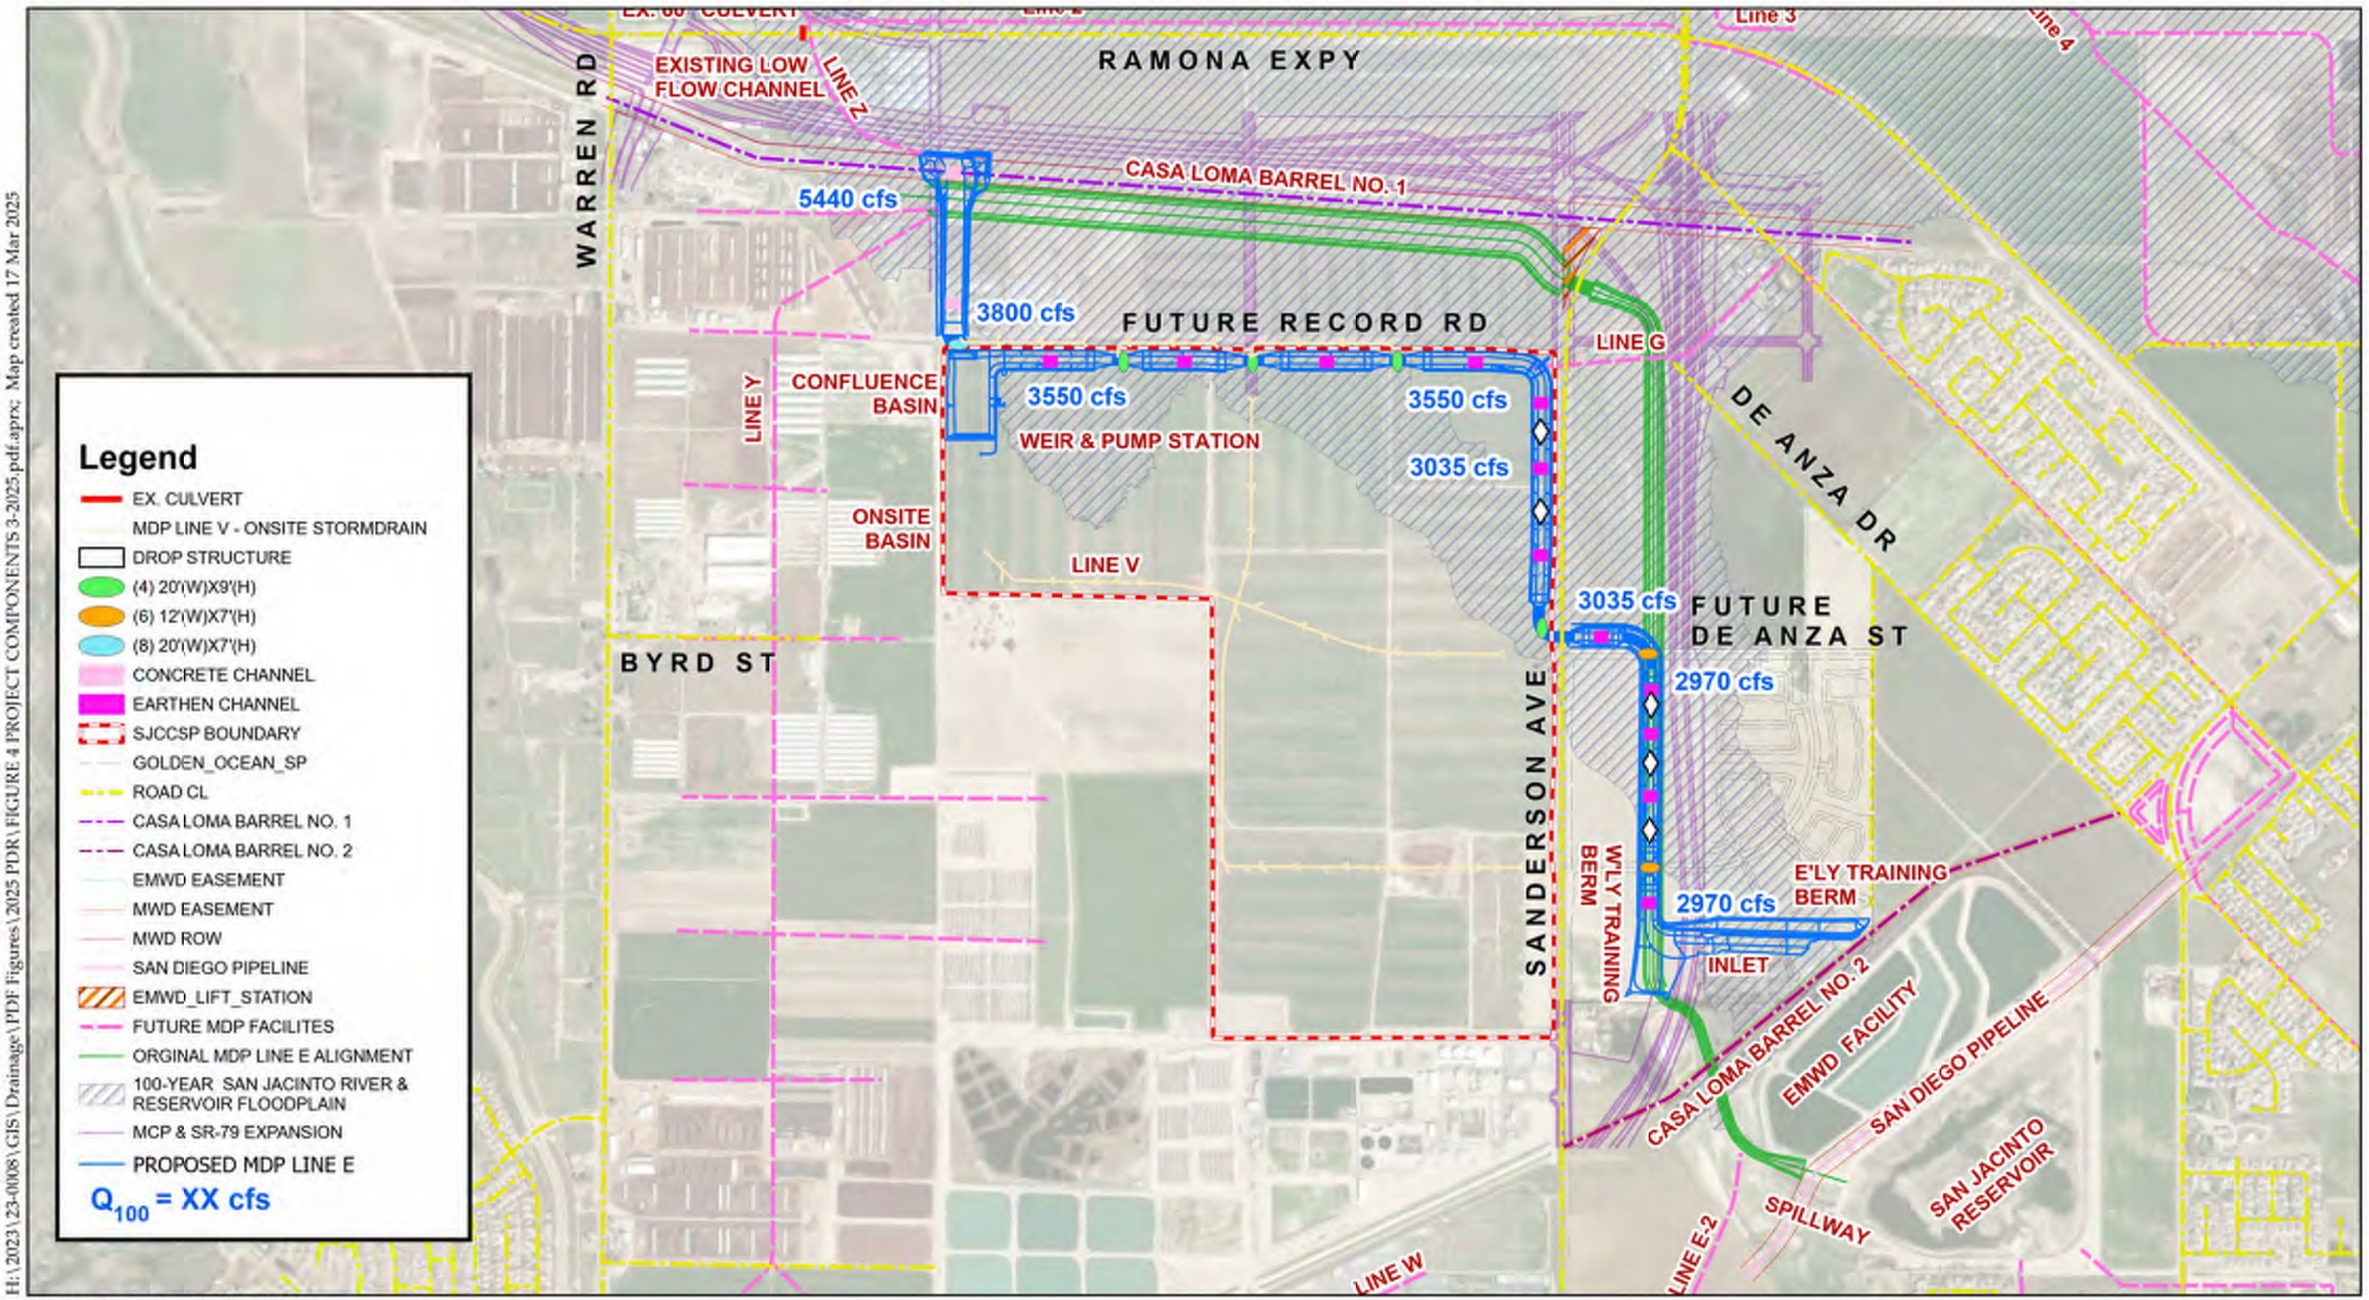
As part of the design of the proposed Project, WEBB held multiple meetings with the City of San Jacinto, RCFC&WCD, MWD, EMWD, SJMD LLC, and Riverside County Transportation Commission (RCTC) to solicit input on the proposed design. In addition, the alignment, hydraulics, and hydrology for the Project underwent two rounds of review with RCFC&WCD prior to submittal of this PDR; the first comment letter dated October 20, 2023, *MS 212 San Jacinto MDP Line E Plan Check No. 1* (LAN, Inc.), and the second comment letter dated December 18, 2023, *MS 212 MDP Line E Plan Check No. 2* (LAN, Inc.).

RCFC&WCD reviewed the full PDR via a comment letter dated February 9, 2024, MS 212 MDP Line E Plan Check No. 3 (LAN, Inc.). An additional review was completed in April 16. 2024. A maintenance, revised alignment, and hydraulics review was completed by RCFC&WCCD via Check No. 4 dated October 3, 2024.

There have been 2 reviews conducted by MWD. The first submittal to MWD was on November 8, 2024, where MWD reviewed the PDR, Geotechnical Report, and Structural Report. MWD gave technical comments on the Geotechnical and Structural Report. The second submittal to MWD was on February 14, 2025, with MWD approval on March 3, 2025. See **Appendix B** for approval email from MWD substructures group.

Section 2 Proposed Project

Line E is an implementing project of the MDP and has been analyzed at a programmatic level in a 2013 EIR and will be analyzed at a project level in a forthcoming EIR addendum. Construction of Line E does not remove properties from the 100-Year floodplain of the San Jacinto River. This will be accomplished by elevating them from the San Jacinto River Floodplain.



2.1 Location

The study components of this PDR are shown in ***Figure 4*** ("Project"). Line E begins downstream of the San Jacinto Reservoir Spillway and north of the Casa Loma Barrel No. 2 easement,[1] continuing north as an earthen trapezoidal channel parallel to, and east of, Sanderson Avenue through an agricultural property owned by Golden Ocean Realty (APN 436-030-001), turning west underneath Sanderson Avenue and turning north, then west before Record Road on the SJCCSP property to the proposed Confluence Basin (a proposed MDP facility). The outflows from the proposed Confluence Basin are conveyed northerly across Casa Loma Barrel No. 1 and outflow to an existing low-flow drainage channel that will, at some point in the future, be constructed as an ultimate MDP facility (Line Z) but is currently in interim condition.

The Project components are summarized as follows and shown on ***Figure 4***:

- 200 linear feet of concrete trapezoidal channel outside of the SJCCSP property crossing the MWD Casa Loma Barrel No. 1 right-of-way with 20-foot-wide access roads on both sides of the channel, a channel base width of 155 feet, channel height of up to 5.5-feet, and channel side slopes that vary from 10:1 to 23:1 ratio, and 560-feet MWD easement width. This segment of the channel will provide access to easterly and westerly MWD access roads from Record Road;
- 1,122 linear feet of concrete trapezoidal channel outside of the SJCCSP property with 20-foot-wide access roads on both sides of the channel, a channel base width of 155-feet, channel height of up to 5.5-feet, and channel side slopes with 1.5:1 ratio, and total right-of-way width of 270-feet for segment Record Road to MWD RW;
    - Includes a set of eight-cell 20-feet wide by 7-feet high RCB crossing Record Rd.;
- One (1) MDP Confluence Basin with 57.5 acre-feet capacity over an area of 6.25 acres, with 72-hour drawdown;
    - Includes a City maintained pump station located on the Confluence Basin parcel to drain the Confluence Basin as well as the SJCCSP Onsite Basin;

[1] Casa Loma Barrel (or "Siphon") Nos. 1 and 2 are buried water pipelines owned and operated by The Metropolitan Water District of Southern California (MWD).

MDP LINE E

ALBERT A. WEBB ASSOCIATES

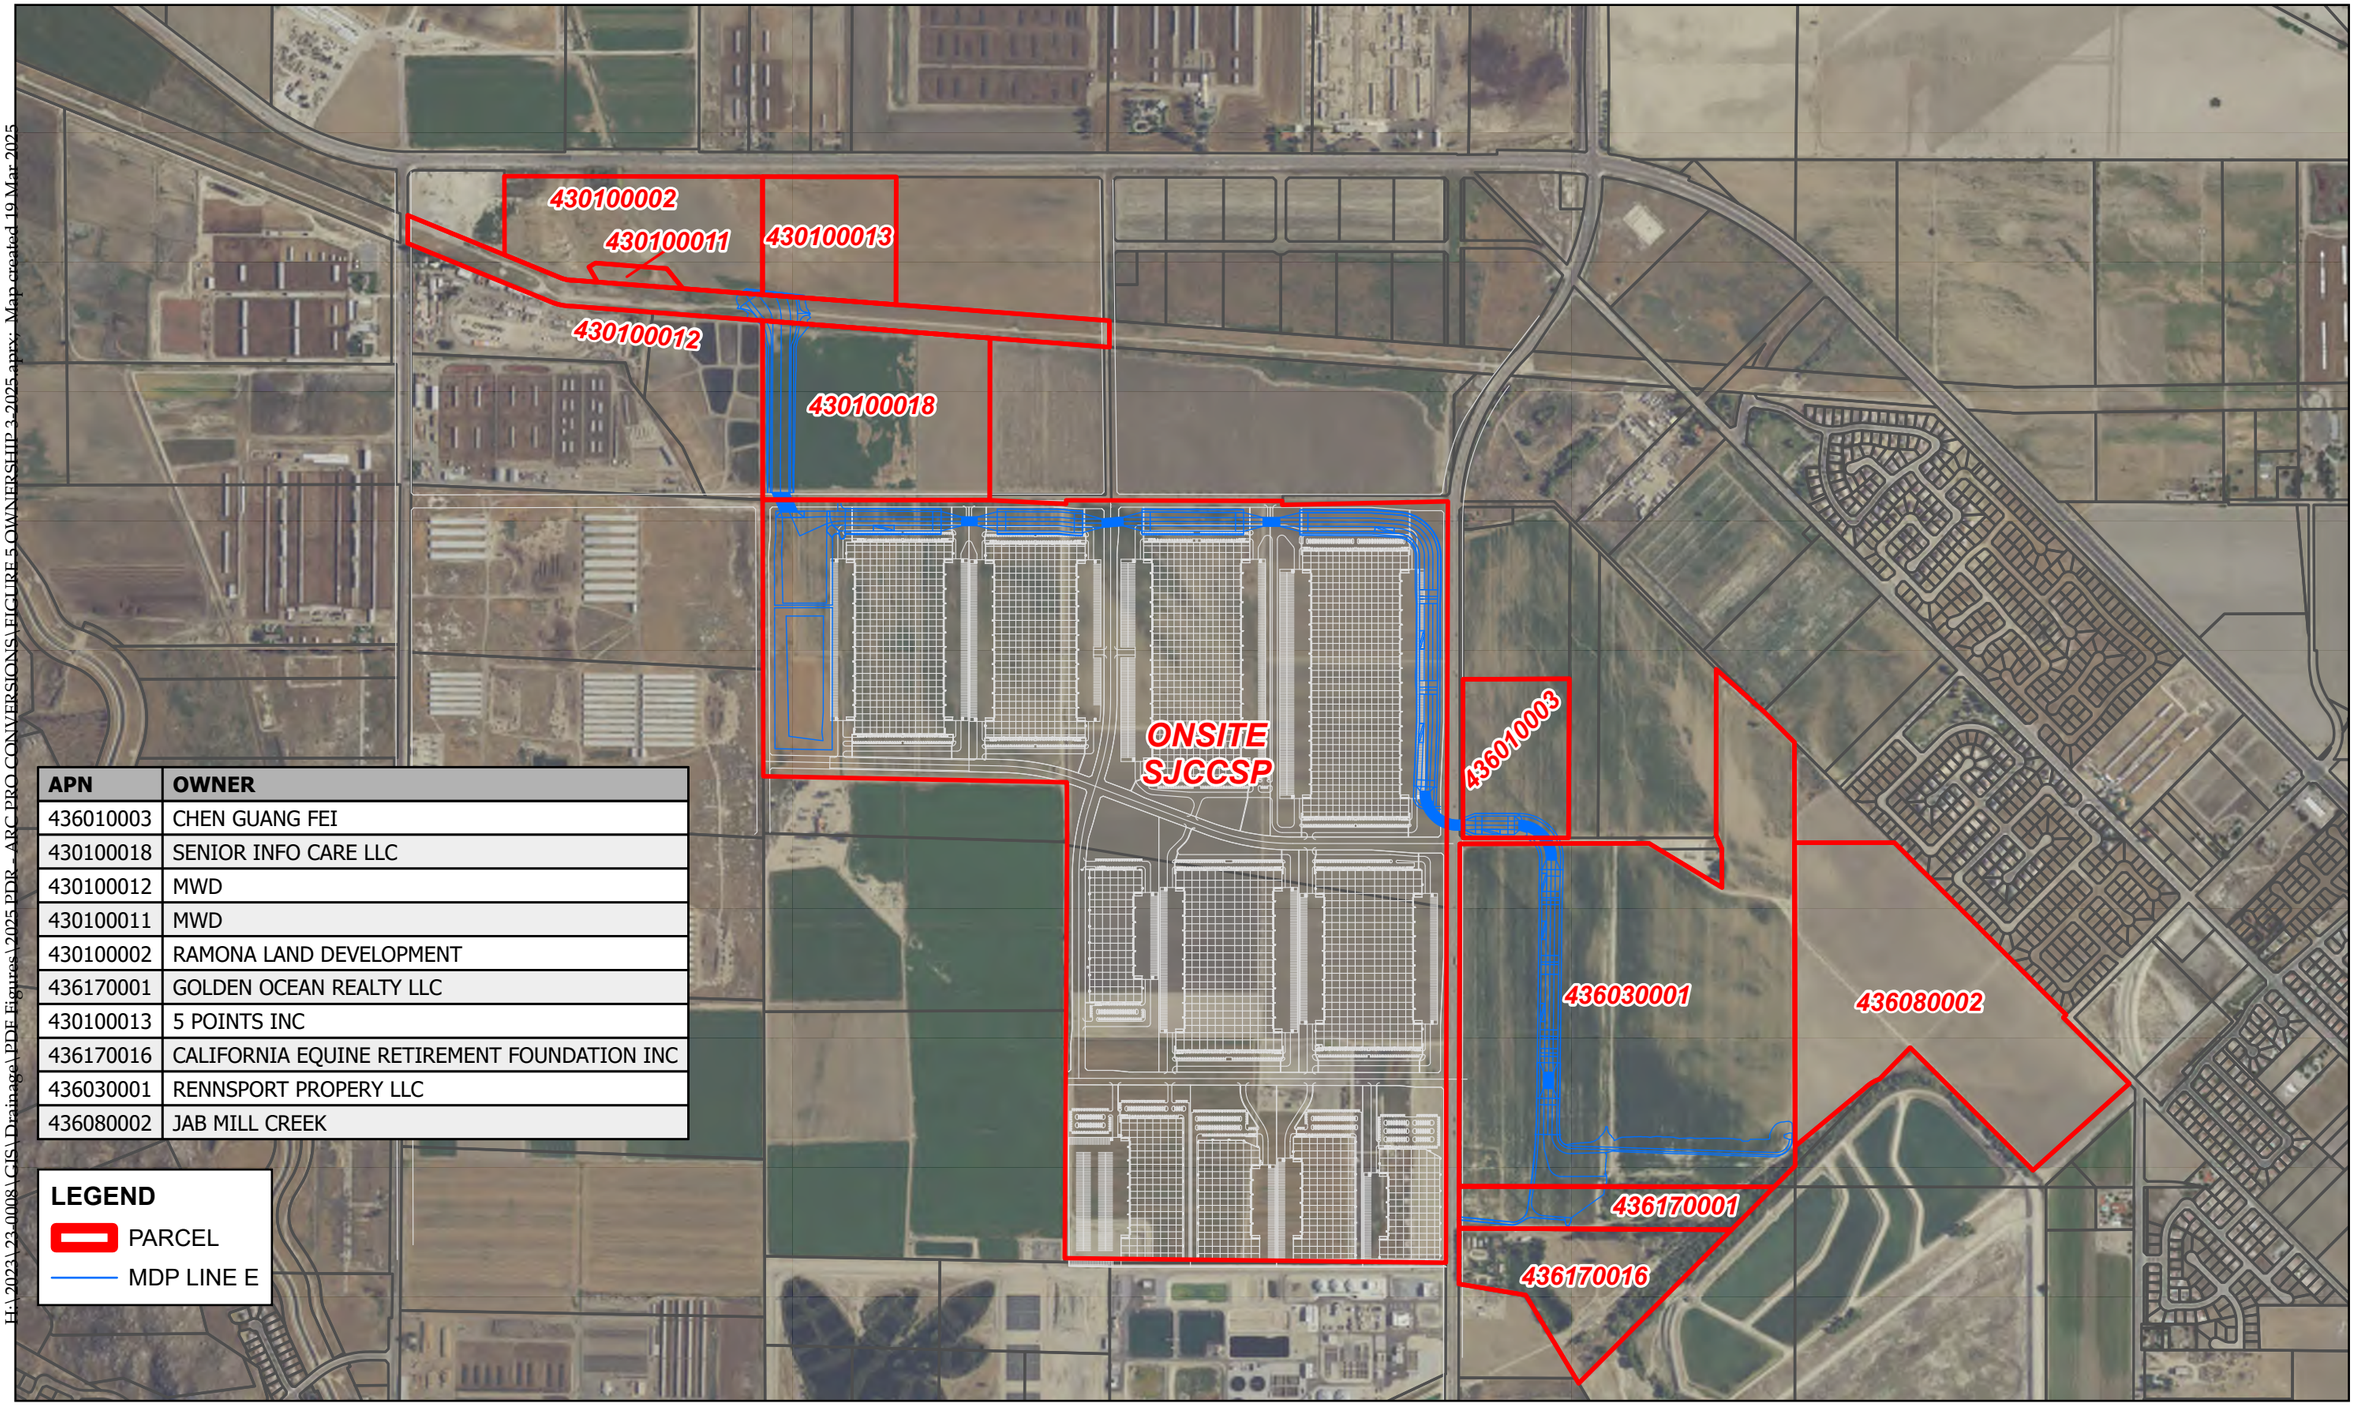
- 4,468 linear feet of earthen trapezoidal channel within the SJCCSP property with 15-foot-wide access roads on both sides of channel, a channel base width of 65-feet, channel height of up to 10-feet, and channel side slopes with 4:1 ratio, and total right-of-way width of 200-feet wide;
    - Includes three sets of four-cell 20-feet wide by 9-feet high RCB and concrete transition structures;
    - Dead storage within the channel is 7.1 acre-ft for approximately 5,180-ft of channel length;
- 1,398 linear feet of earthen trapezoidal channel outside of the SJCCSP property with 20-foot-wide access roads on both sides of channel, a channel base width of 65-feet, channel height of up to 10-feet, and channel side slopes with 4:1 ratio, and total right-of-way width of 200-feet wide east of Sanderson Avenue;
    - Includes three sets of six-cell 12-feet wide by 7-feet high RCB and concrete transition structures, each for future road crossings;
- Two (2) earthen training berms with 20-foot-wide access roads on top of each and each with 2:1 slope on the wet side of the training berms and 20:1 slope on the dry side of the berms: approximately 900 linear feet of Westerly Training Berm and approximately 1,514 linear feet of Easterly Training Berm;
- Five (5) sloped rip-rap drop structures;
- One (1) 14-feet wide by 7-feet high stub-out RCB connection for future MDP Line G and includes channel paving and scour protection; and
- The geotechnical and structural engineering details for the Line E crossing over Casa Loma Barrel No. 1 will be provided in **Appendix B**. WEBB is currently processing an easement application with MWD on behalf of RCFC&WCD for review and approval of the crossing of MWD's right-of-way. More details will be provided in the final design (Kleinfelder).

The proposed on-site drainage system for SJCCSP is identified as the "Line V onsite system" and includes an "Onsite Basin" for onsite runoff (see ***Figure 4***). Outflows from the SJCCSP Onsite Basin will outlet to the proposed Confluence Basin and downstream Line E, as described herein.

2.2 Design Rationale

The proposed Project presents a slightly different alignment than what was originally included in the MDP. This is the result of a process to engineer around constraints that were identified during stakeholder meetings (see *Section 1.1*) in order to improve the design from what was originally proposed. Specifically, the proposed alignment intentionally avoids the EMWD and MWD easements for pipelines located near the Project inlet, and, at the same time avoids the riparian habitat around the north side of the San Jacinto Reservoir. This has resulted in no hard connection between Line E and the San Jacinto Reservoir Spillway, as well as no hard connection between Line E and Line E-2. Maintenance access within private property has been considered and provided for in the Project, as discussed herein. There is preliminary evidence of biological resources on the Chen Fei property (APN 436-010-003) located north of the proposed Golden Ocean Realty properties (APNs 436-030-001 and 436-170-001), as well as

potentially environmentally sensitive areas along the south side of the Casa Loma Barrel No. 1 MWD right-of-way west of Sanderson Avenue, both of which the Project will avoid with the proposed design. Evaluations of sensitive biological resources have been conducted as part of the Project CEQA analysis and are not included herein. Because WEBB is preparing the CEQA documentation on behalf of the City, this information is provided quickly to WEBB engineers working on this design. The proposed Project also took into consideration several future projects planned by public agencies in the same area, such as RCTC and EMWD and was realigned to avoid conflicts with major sewer infrastructure located at where the MDP planned a crossing of Sanderson Avenue near the De Anza Lift Station. Furthermore, through the willingness of SJMD, LLC to allow part of the Project on its SJCCSP property, right-of-way acquisition is simplified and better controlled. The City will maintain Line E Channel within the SJCCSP property, the proposed Confluence Basin and pump station. The proposed Project has different flow rates than the MDP, which are presented and justified herein. The result of the proposed Project meets the objective to remove flooding risk to the area from the upstream tributary area and Line E conveys up to and including the modeled 100-Year flow rates within the design parameters required by RCFC&WCD.



WEBB researched the location of existing utilities in the Project area and they are shown on the Long-Axis Plan in **Appendix A**. The existing utilities in conflict with the proposed RCB's crossing Sanderson Avenue will be relocated and relocation plans will be prepared during the final design phase. Proposed utility crossings will be coordinated with adjacent developers and projects during final design, to the extent that information is available when the design is being prepared.

2.3 Access and Easements

The Project includes 20-foot-wide access roads for vehicle access to these MDP components located outside of the SJCCSP: the training berms, channel and RCBs. Additionally (2) 20-foot-wide access roads will be provided to access the easterly and westerly maintenance roads within MWD's fee right-of-way. Proposed MDP facilities within the SJCCSP will have 15-foot-wide access roads. RCFC&WCD does not own the land where the MDP facilities are proposed, as shown on ***Figure 5***. Therefore, dedication of rights-of-way by each property will be required and will be completed in final design.

SJMD, LLC and Golden Ocean Realty have indicated their intentions to dedicate a fee parcel on their respective properties to RCFC&WCD. Other private parcels are being evaluated. The selected alignment substantially reduces the number of private parcels and potential for eminent domain. The proposed Line G stub out will require an easement if located outside of RCFC&WCD right-of-way.

An easement will also be required across the MWD property at Casa Loma Barrel No. 1, estimated at 200 feet long by 600 feet wide. Procuring the easement from MWD will be completed in the final design phase.

2.4 FEMA Flood Plain Zone

A portion of the study area is located within FEMA flood plain zone AE corresponding to the San Jacinto River flood zone, as shown in ***Figure 6***. Zone AE represents areas in the 100-Year event flood plain with a Base Flood Elevation (BFE) or depth. This flood plain zone is designated consistent with the Letter of Map Revision (LOMR) no. 21-09-1682P, effective November 9, 2022.

The San Jacinto Reservoir is identified as FEMA flood plain zone A, which represents a 100-Year flood plain without BFE.

As part of the development of the SJCCSP and after approval of this PDR, a Conditional Letter of Map Revision (CLOMR) will be submitted to the Federal Emergency Management Agency (FEMA) requesting a Letter of Map Revision (LOMR) to revise the current National Flood Insurance Plan (NFIP) map to change the flood plain boundaries such that the SJCCSP site is no longer within a flood hazard zone. A portion of the SJCCSP will have to be elevated in order to remove it from the San Jacinto River 100-Year floodplain; however, that is not a part of this PDR.

2.5 Methodology

Pursuant to the RCFC&WCD Design Manual (March 2024) and L.A. County Hydraulic Design Manual (March 1982), the Project design is based on the required design manuals and design standards for a steady, stable, and open earthen, non-leveed channel that conveys 100-Year flow rate considering capacity and scour potential (i.e., with and without vegetation scenarios). The San Jacinto River 100-Year floodplain was used as the starting water surface elevation (WSE). The proposed SJCCSP drainage system and design methodology are analyzed under separate cover as part of entitlement with the City of San Jacinto.

2.5.1 Hydrology

Hydrologic calculations were performed consistent with the RCFC&WCD Hydrology Manual, dated April 1978. The rational method and synthetic unit hydrograph methods were used to determine peak flow rates. Rational method and synthetic unit hydrograph calculations were performed using CivilDesign® software, which incorporates the hydrological parameters outlined in the RCFC&WCD Hydrology Manual. Hydrological parameters (i.e., rainfall values and soil types) were determined from the RCFC&WCD Hydrology Manual.

2.5.2 Hydraulics

Water Surface Pressure Gradient (WSPG) is a hydraulic model from CivilDesign® used to preliminarily size the proposed channel. The various Project constraints were then evaluated against the results of the WSPG model. Stakeholder input on the proposed design led to the development of additional hydraulic modeling to verify the results. Hydrologic Engineering Centers River Analysis System (HEC-RAS) Version 6.3 developed by the U.S. Army Corps of Engineers was used to model the hydraulics of water flow through the channels. Two different HEC-RAS models were used in this study: one-dimensional (1D) HEC-RAS for the proposed channel and two-dimensional (2D) for the proposed channel inlet and proposed low flow channel located at the channel outlet.

The RCFC&WCD Hydraulic Design Manual, the L.A. County Hydraulic Design Manual dated March 1982, and the U.S. Department of Transportation HEC 14-Hydraulic Design of Energy Dissipators for Culverts and Channels dated July 2006 were used for this study.

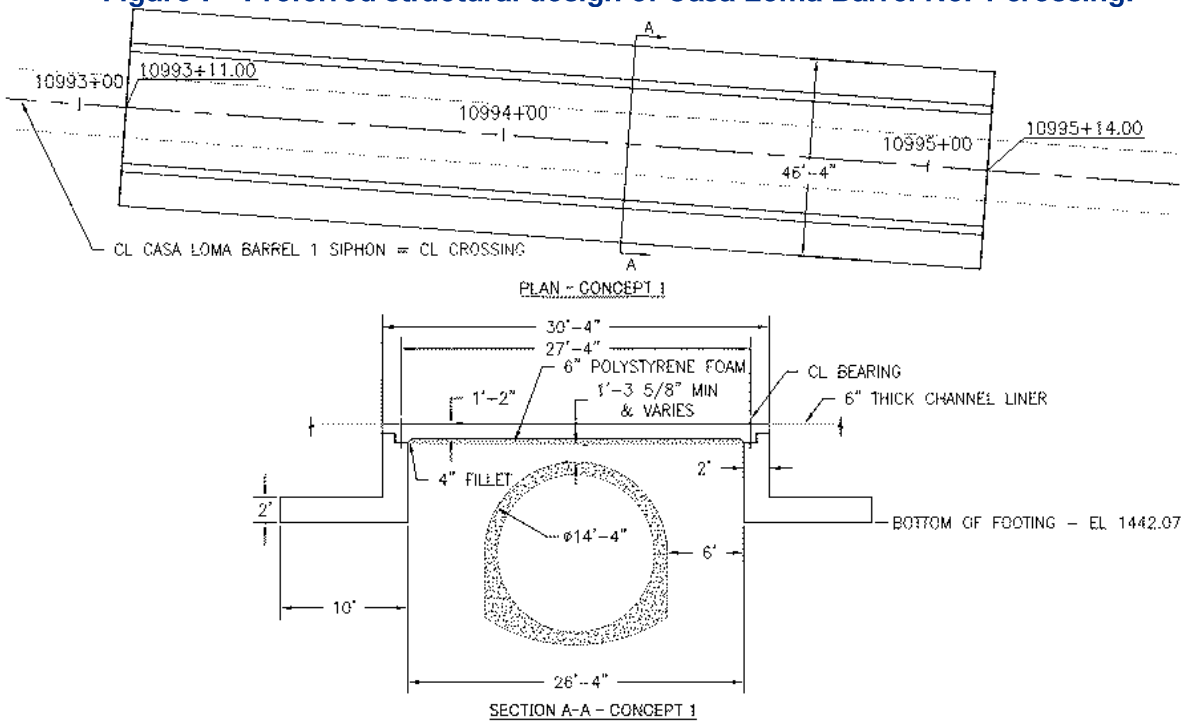
2.5.3 Geotechnical Considerations

A Geotechnical Investigation Report for the San Jacinto Line E Storm Drain project was prepared by Kleinfelder, Inc. (a copy of the report is included in **Appendix B**). The purpose of the investigation was to evaluate surface and subsurface conditions in the area of planned improvements and to provide geotechnical recommendations for earthwork, design, and construction considerations (Kleinfelder, p. 1). The study found depth to groundwater varies in the project area but was found to be below the invert of the proposed Line E channel for the majority of its length. The exception is at the southern end where the groundwater is 8-9 feet deep below existing ground at Boring B-16, which is located several hundred feet to the east of the proposed channel alignment. However, Boring B-19 at the Line E inlet shows a

depth of 17 feet. Additional investigation will be conducted during final design to confirm the depth of groundwater at the channel, and what mitigation methods, if any, are needed. Also, the depth of groundwater at the easterly training berm (Borings B-17 and B-18) is shallow, which will need to be accounted for during the construction of any cutoff walls and resolved in final design. The groundwater based on these borings is plotted on the Long Plot in **Appendix A**.

Excerpt showing locations of borings from "Figure 2 - Exploration Location Map" (Kleinfelder, Dec. 5, 2023).

The Geotechnical Study also provided data on soil classifications, which is used to determine the appropriate Manning's "n" values with the RCFC Design Manual. The borings drilled adjacent to the northerly MWD right-of-way (Casa Loma Barrel No. 1) will inform preliminary designs of a crossing structure, the MWD-approved geotechnical report (and structural) can be found in **Appendix B**.



Based on the results of the field explorations, laboratory testing, and engineering analyses conducted during the geotechnical study, it is the professional opinion of Kleinfelder, Inc. that the proposed project is geotechnically feasible provided the recommendations presented in the report are incorporated into the project design and construction (Kleinfelder, p. 14).

2.5.4 MWD Casa Loma Barrel No. 1 Crossing

At the outlet of this project, we cross MWD fee property and MWD facility Casa Loma Barrel No. 1 which was constructed in the 1920s and provides half of the potable water from the Colorado River. Casa Loma Barrel No. 1 is a critical facility that MWD requires near zero settlement and rebound. Kleinfelder completed a preliminary geotechnical investigation and a preliminary structural design report. The result of the geotechnical and structural design report was that the crossing is feasible and constructible. The preferred structural crossing of Casa Loma Barrel No. 1 is shown in ***Figure 7*** below. The concept is a spread footing with a slab

(similar to a bridge deck) spanning Casa Loma Barrel 1. This design will allow future work on Casa Loma Barrel No. 1 without reconstructing the entire crossing. MWD approved the geotechnical and structural reports in March 2025, the approval email and reports are included in **Appendix B**. It should be noted that there is scour protection in the form of the sloped cutoff wall at the downstream edge of the MWD right of way. Paralleling the MWD right of way there is a concrete channel that will convey all low flows northerly.

Figure 7 - Preferred structural design of Casa Loma Barrel No. 1 crossing.

Section 3 Hydrology

3.1 Existing MDP Hydrology

The existing MDP hydrology is based on the *Master Drainage Plan Update for San Jacinto Valley West Area* prepared by WEBB and dated May 2007 (updated October 2008). The hydrology analysis for Line E segment related to the SJCCSP began with the existing MDP model flow rates and facilities to represent the "existing condition." Contributing flows to Line E include overflows from the San Jacinto Reservoir, tributary flows from MDP N Line E-2 located south of Line E, future MDP Line G, future MDP Line V, and future MDP Line Y. The existing conditions for Line E flow rates have accounted for the following contributing flows (refer to ***Figure 8*** and **Appendix C**):

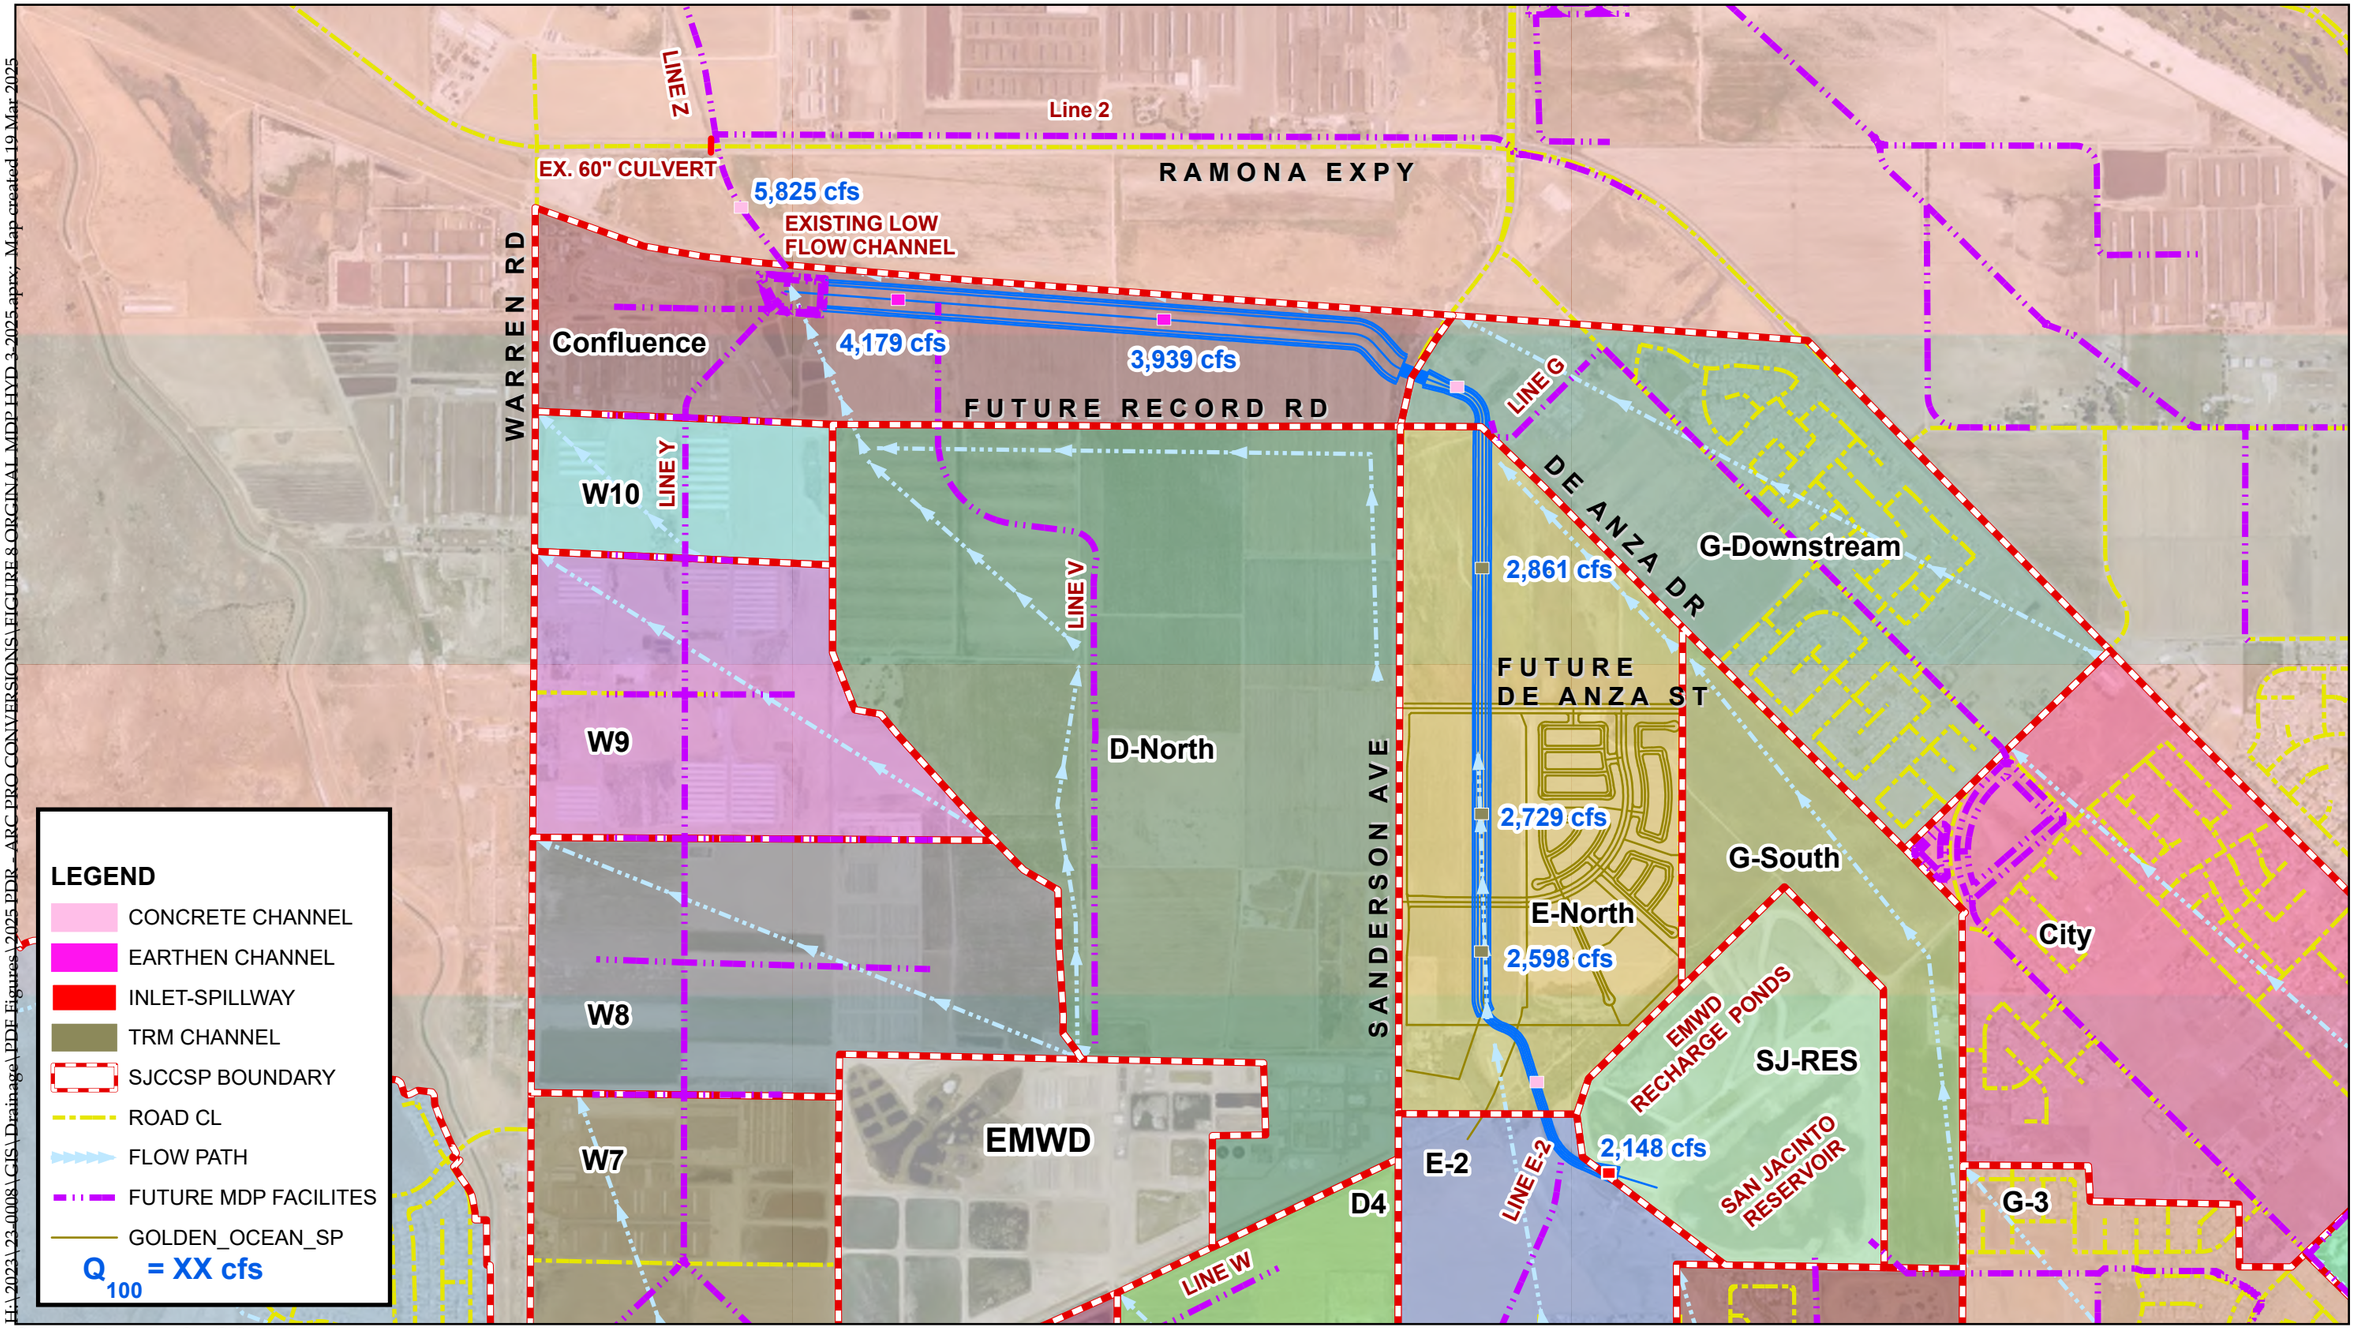


Table 1 – Existing MDP Hydrology

MDP Components	Existing MDP Flow Rates
Overflow from San Jacinto Reservoir	Q_{100} = 2,148 cfs
MDP N Line E-2	Q_{100} = 686 cfs; Trap B=6', D=6', Z=1.5
Golden Ocean Property contribution	Q_{100} = 521 cfs, RCP 14' (W) x 7' (H), assuming slope = 0.1%
MDP Line G	Q_{100} = 518 cfs; RCB 8' (W) x 4' (H)
MDP Line V On-Site System	Q_{100} = 962 cfs; Trap B=60', D=5', Z=4
MDP Line Y	Q_{100} = 1,646 cfs
Channel Segments	
Spillway to Line E-2	Q_{100} = 2,148 cfs
Line E-2 to Golden Ocean Property	Q_{100} = 2,598 cfs
Golden Ocean Property to Future De Anza St	Q_{100} = 2,729 cfs
Future De Anza St to Line G	Q_{100} = 2,861 cfs
Line G to Line V	Q_{100} = 3,939 cfs
Line V to Confluence Basin	Q_{100} = 4,179 cfs
Flow over Northerly MWD ROW	Q_{100} = 5,825 cfs

Note: cfs = cubic feet per second; MDP = Master Drainage Plan; RCP = reinforced concrete pipe; RCB = reinforced concrete box; W = width; H = height; Trap = trapezoidal.

(a) "Q_{100}" means the flow rate in a 100-Year storm event.

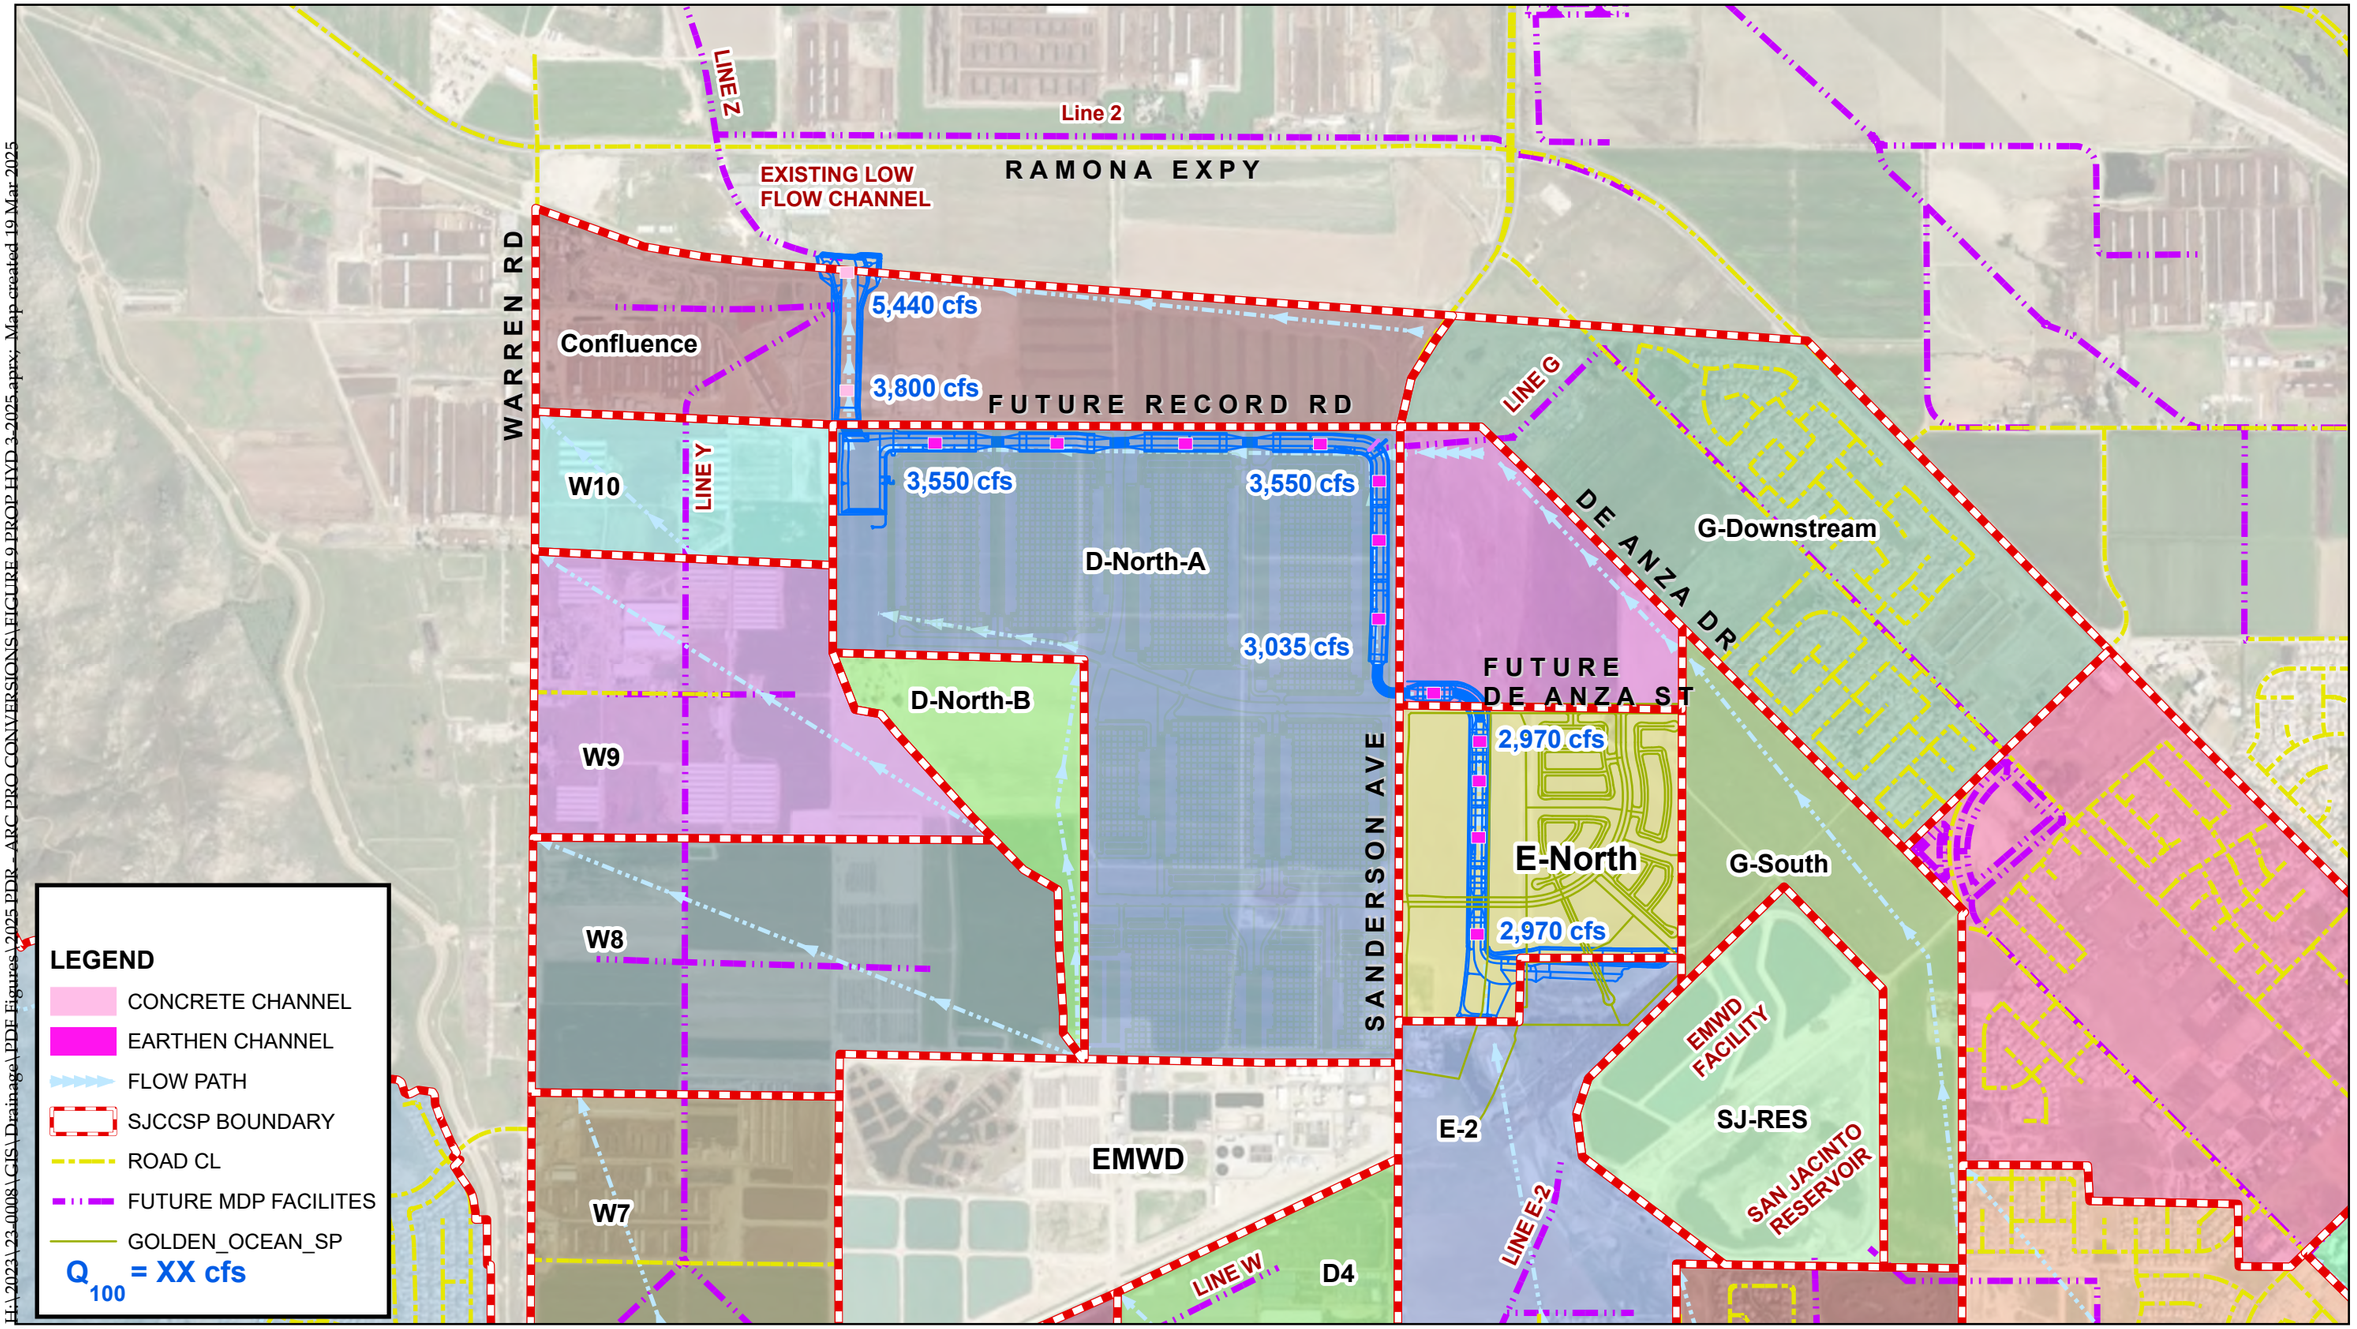
3.2 Proposed MDP Hydrology

The unit hydrograph analyses in this report were prepared in accordance with the methodology outlined in the RCFC&WCD Hydrology Manual dated April 1978. Because the Hydrology Manual includes precipitation data that has been superseded, the rainfall values used in the 2007 MDP Update as well as this study come from the NOAA Atlas 14 Version 4.0. All hydrology is based on a 100-Year 24-hour flood event.



The same watershed subareas that were delineated in the 2007 MDP Update are also used for this study, as shown on ***Figure 9*** and Appendix C; however, with some updates, as follows:

- Subarea E-2 land use updated to reflect actual site conditions of horse property;
- The land use was updated from residential to commercial for the SJCCSP property; and
- Subarea D-North of the wastewater treatment plant property was removed because runoff from this area will be collected and treated by the wastewater facility.

The result of these updates is a decreased flow rate reaching Line E compared to the 2007 MDP Update. The proposed Line E design rearranged how tributary flows will be collected, as follows:

- With the proposed design, tributary flows from the south are directed to Subarea D-North-A and then into a proposed Onsite Basin or Confluence Basin to be pumped out to Line E north of Record Road (***Figure 9***);
- Proposed MDP Line Y will no longer join the Confluence Basin and will instead join Line E upstream of Casa Loma Barrel No. 1;
- Flows from the Confluence Subarea are being added to Line E in the area of Casa Loma Barrel No. 1, which was previously coming into Line E at Sanderson Avenue under the prior MDP;
- Line G is proposed on the opposite side of Sanderson Avenue as compared to the MDP;

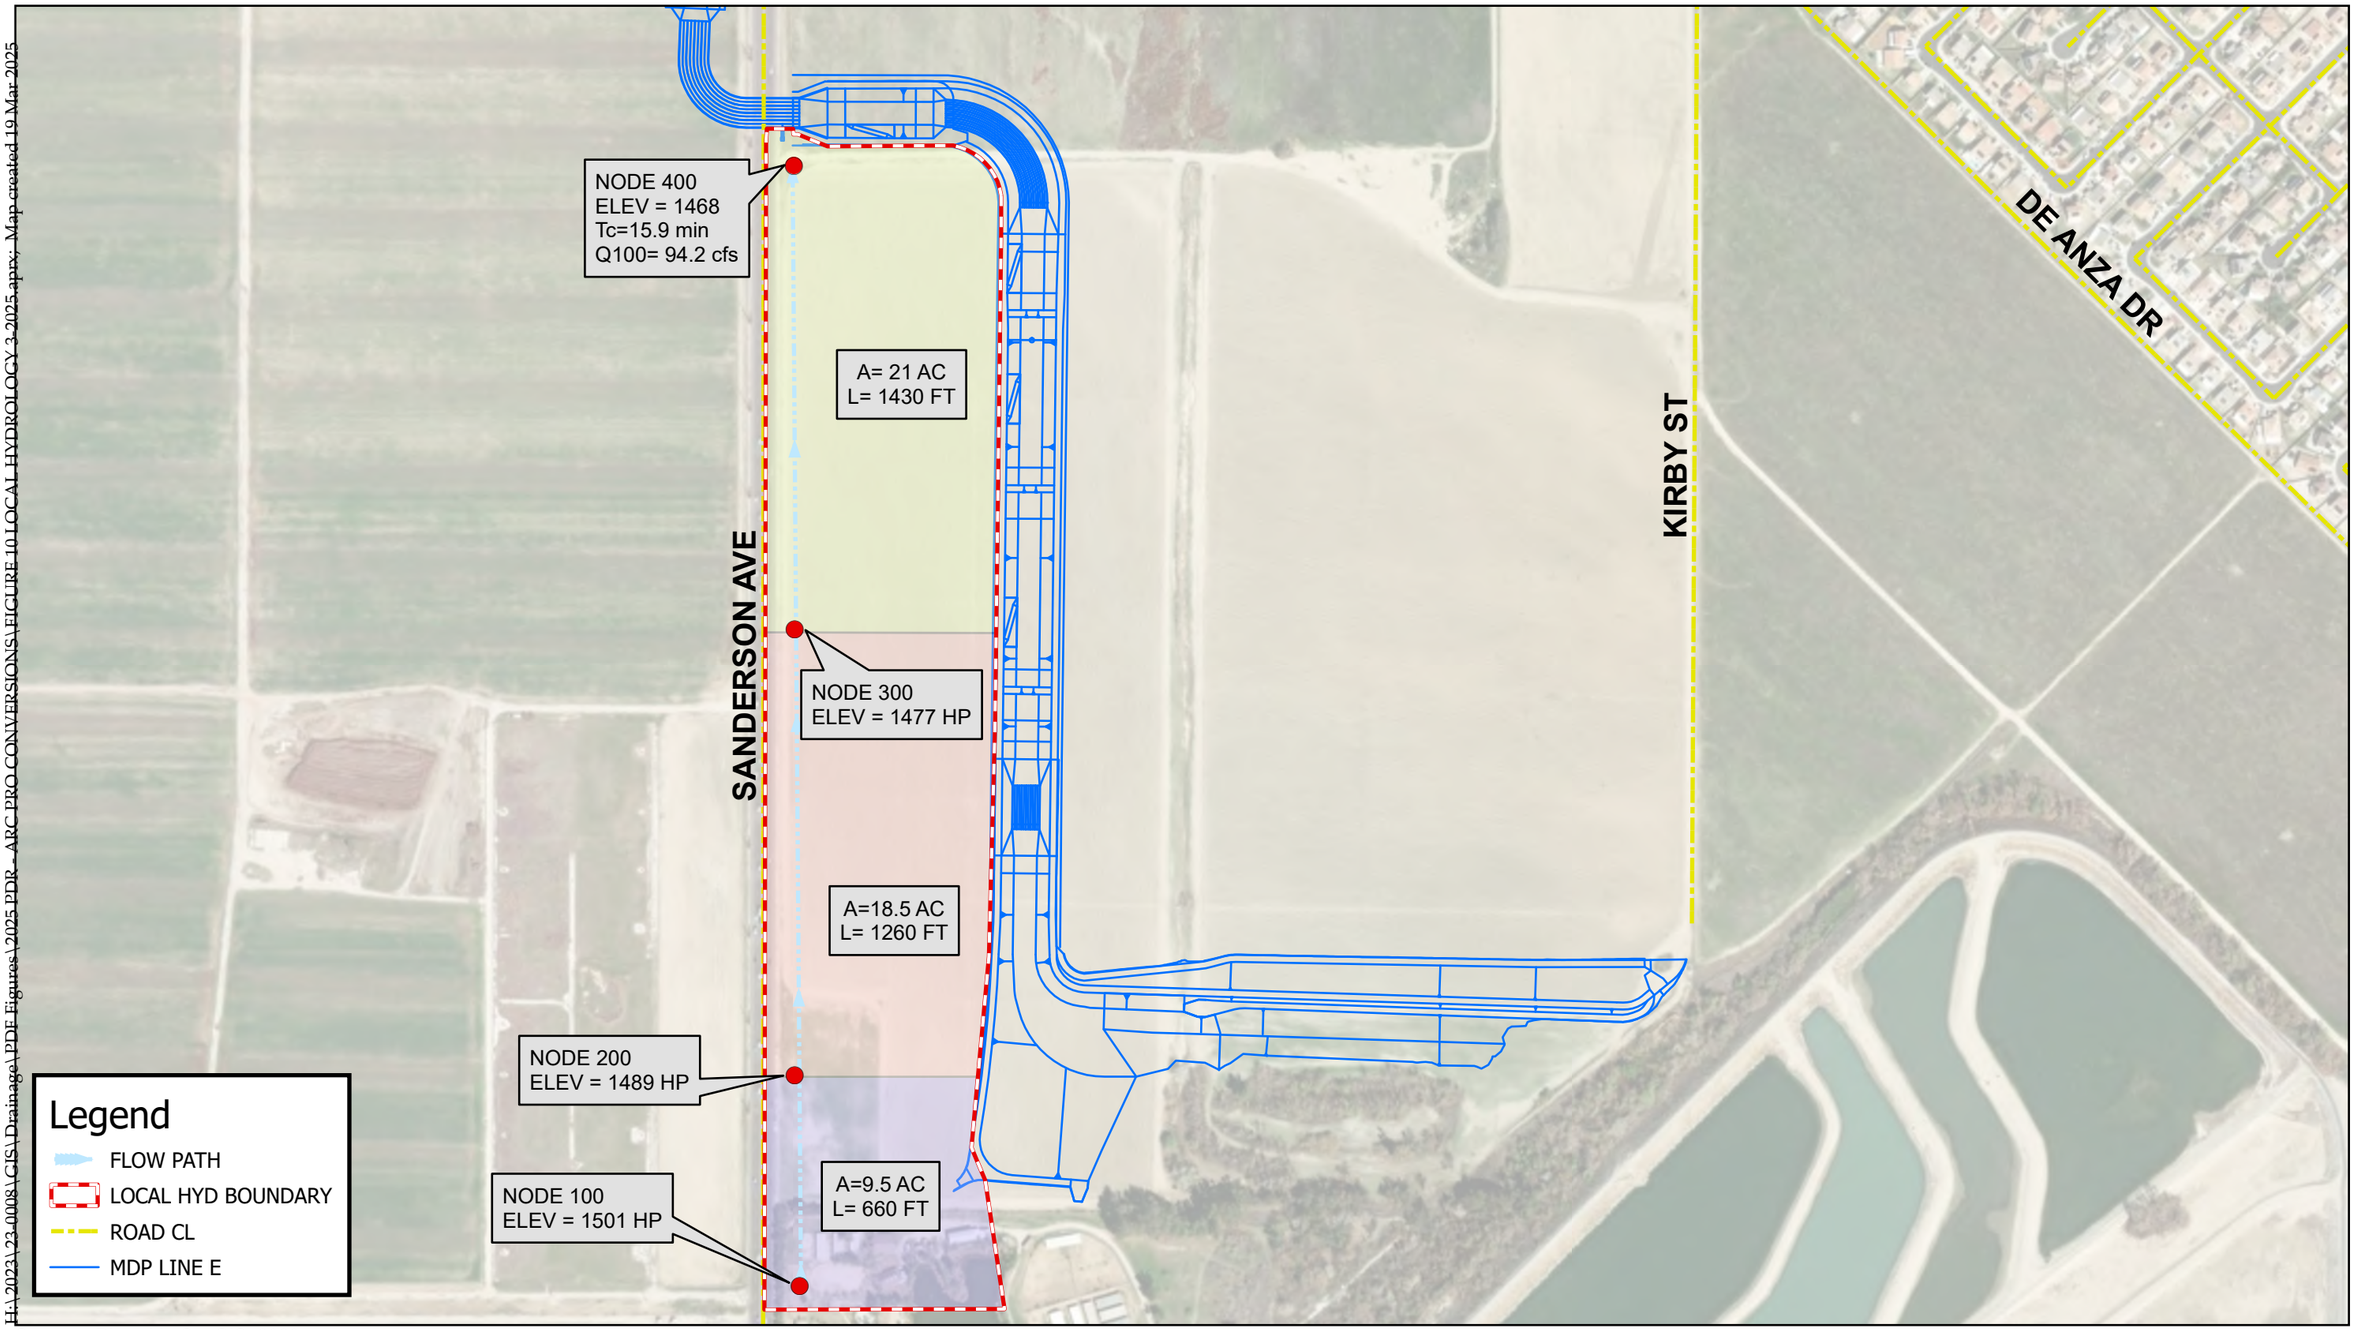
3.2.1 Design Flow Rates

The Project design flow rates for MDP components and Line E channel segments are shown in ***Table 2***. Refer to ***Figure 9*** and **Appendix C** for backup.

Table 2 – Proposed MDP Flow Rates

MDP Components	Revised Flow Rates
Overflow from San Jacinto Reservoir	Q_{100} = 2,148 cfs
MDP N Line E-2	Q_{100} = 527 cfs; Trap B=6', D=6', Z=1.5
Golden Ocean property contribution	Q_{100} = 295 cfs, RCP 14' (W) x 7' (H), assuming slope = 0.1%
MDP Line G	Q_{100} = 580 cfs; RCB 14' (W) x 6' (H)
MDP Line V On-Site System	Q_{100} = 1440 cfs; Onsite drainage system & detention basin
MDP Line Y	Q_{100} = 1,646 cfs
Proposed Channel Segments	
Inlet to Future De Anza St	Q_{100} = 2,970 cfs
Future De Anza St to Future Record Rd	Q_{100} = 3,035 cfs
Future Record Rd to Confluence Basin	Q_{100} = 3,550 cfs
Line Y Confluence	Q_{100} = 3,800 cfs
Confluence Basin to Northerly MWD ROW	Q_{100} = 5,440 cfs

Note: cfs = cubic feet per second; MDP = Master Drainage Plan



(a) "Q_{100}" means the flow rate in a 100-year storm event.

3.2.2 Local Hydrology Analysis at Sanderson Avenue

A roadside ditch conveys stormwater along the east side of Sanderson Avenue as shown in the image below. Because the proposed Line E channel would cross Sanderson Avenue and intersect with the existing ditch, the contribution of flow from this roadside ditch to proposed Line E channel was analyzed as part of this study. Results suggest that 49 acres drain to the roadside ditch, as shown in ***Figure 10***. The hydrology subareas are already accounted for in the overall MDP hydrology. A rate of 95 cfs of runoff was generated and was used to size an inlet and 54" RCP lateral to Line E channel. See **Appendix C** for the rational method model results.

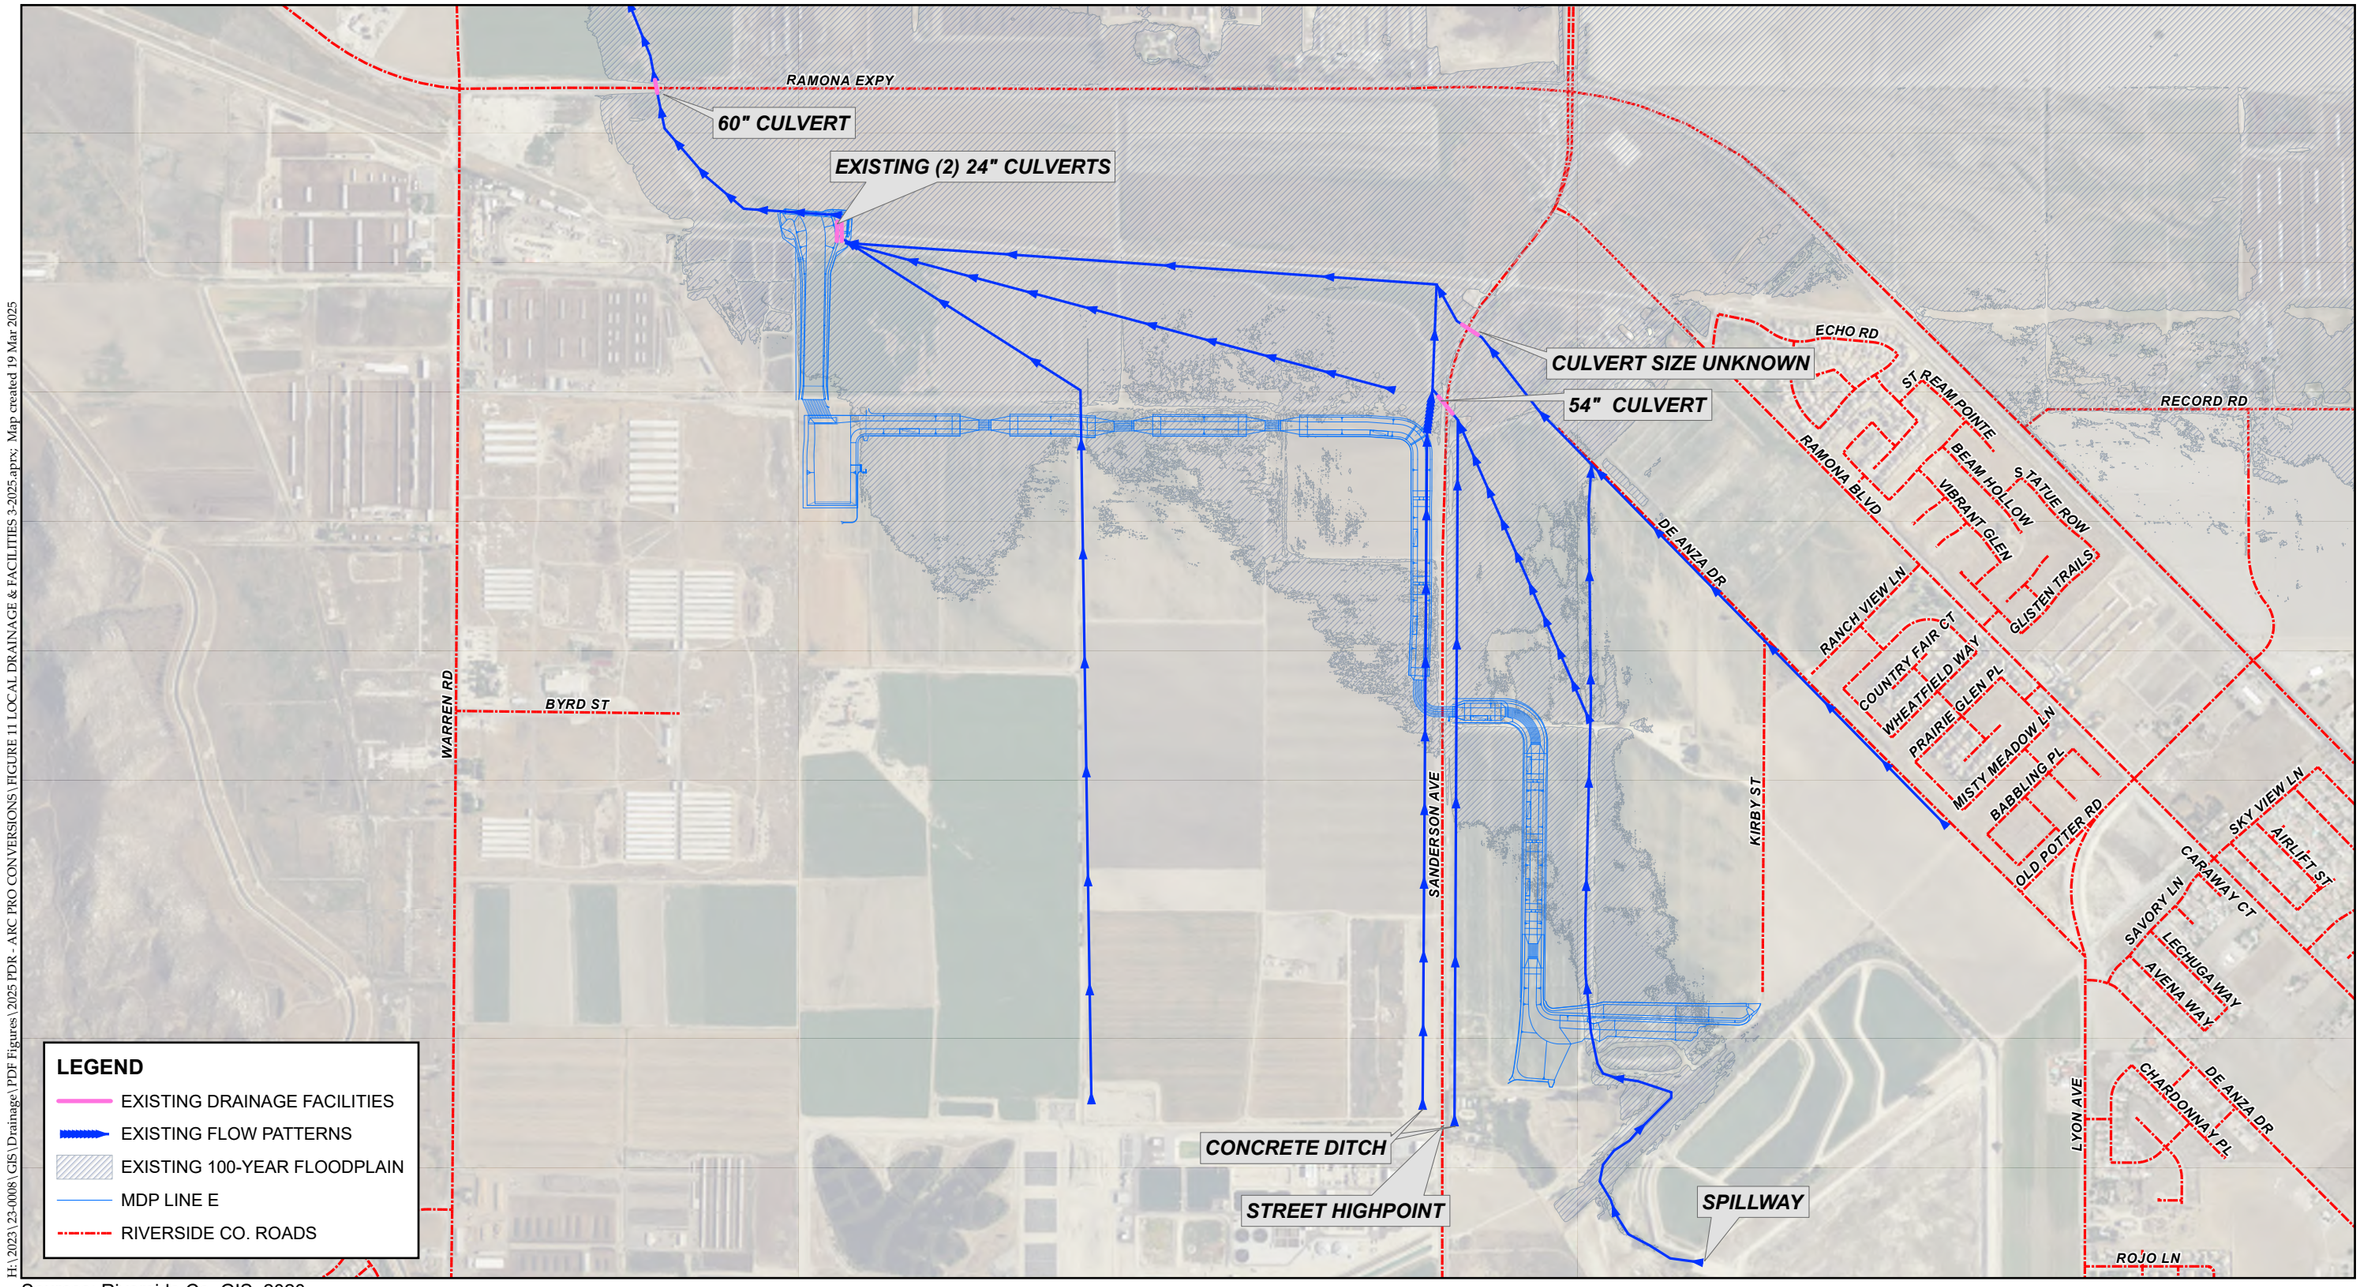

FIGURE 10 - LOCAL FLOW ANALYSIS

MDP LINE E - SANDERSON DITCH INLET

ALBERT A. WEBB ASSOCIATES

3.2.3 Local Flow Pattern at Casa Loma Barrel No. 1

The local drainage pattern is similar to the flow paths illustrated in ***Figure 11***. During small rain events, a significant amount of runoff sheet flows to either side of Sanderson Avenue and is conveyed northerly. As shown in ***Figure 11***, the local existing drainage pattern flows northeasterly eventually to two existing culverts that cross the MWD Casa Loma Barrel No. 1 right of way. Both culverts are 24-inch corrugated metal pipes that sit atop the MWD Casa Loma Barrel No. 1. During any rain event that generates flooding, these culverts are responsible for draining the area south of MWD Casa Loma Barrel No. 1 and bounded by Sanderson Avenue and the EMWD ponds. In the post-project condition, the existing drainage patterns north of Record Road and east of Sanderson Avenue (i.e., east of Line E) will remain. The Project will replace the existing low-flow (2) 24-inch diameter corrugated metal pipes, with (2) 24-inch diameter reinforced concrete pipes that directly outlet into the downstream concrete channel.

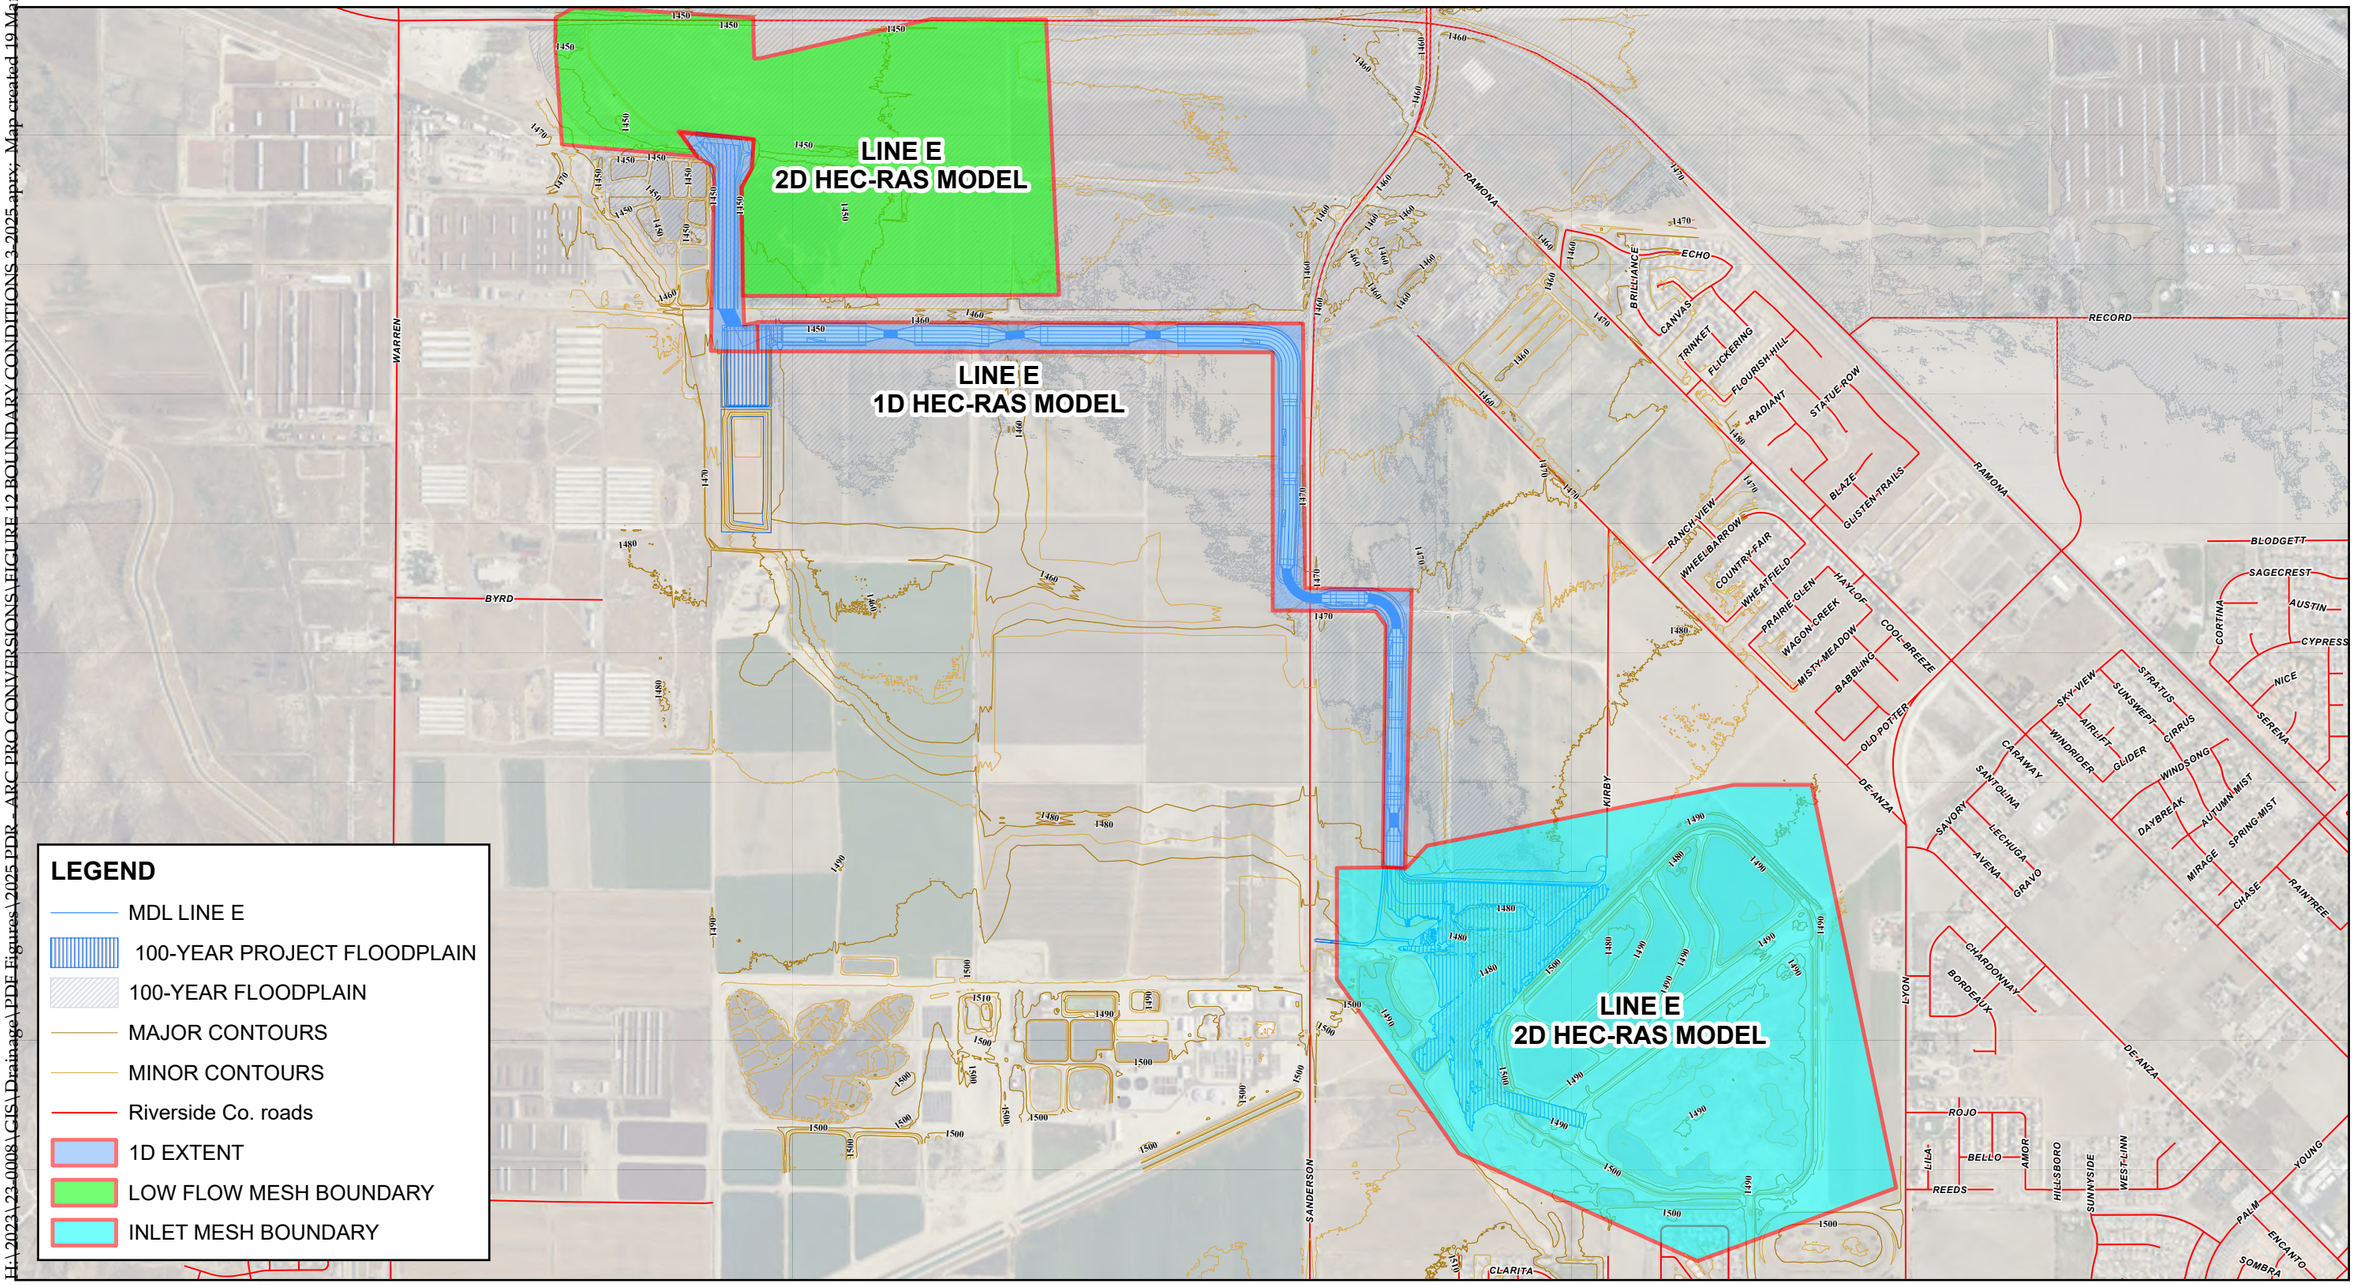
Section 4 Hydraulics

Based upon the design flow rates established in *Section 3* of this report, hydraulic analyses were then conducted to size the proposed updated facilities. One-dimensional (1D) HEC-RAS and WSPG were both used to model the hydraulics of the proposed channel and drop structures. Two-dimensional (2D) HEC-RAS was used to model the hydraulics of the proposed training berms at the upstream end of the project and the low flow channel at the downstream end of the project. Transition length sizing is included in **Appendix D** of this report.

In the existing condition, the San Jacinto Valley MDP is mostly unbuilt, and the Line E piece proposed in this study is upstream and downstream of other planned MDP elements to be constructed by others in the future. Refer to the long-axis plot located in **Appendix A** for the preliminary plan and profile of Line E.



4.1 Model Parameters

4.1.1 Boundary Conditions

This study includes three different HEC-RAS models and a WSPG model, with each model having different boundary conditions. See ***Figure 12*** for a visual of each model's spatial extent. The downstream boundary condition for this study is the 100-Year San Jacinto River floodplain elevation (i.e., 1,452.93 feet amsl) and the starting water surface elevation (WSE) for the Line E earthen channel is dictated by the Confluence Basin (i.e., 1456± feet amsl). Below is the breakdown for each model's boundary conditions. See ***Appendix D*** for HEC-RAS exhibits, modeling parameters, and results.

- WSPG Model
  - Starting water surface elevation is 1452.93 ft for northerly MWD ROW crossing (Casa Loma Barrel No. 1)
  - Starting water surface elevation is 1456.15 ft for Line E earthen channel
- 1D HEC-RAS Line E Channel
  - Starting water surface elevation is 1452.93 ft for MWD ROW crossing (Casa Loma Barrel No. 1)
  - Starting water surface elevation is 1456.10 ft for Line E earthen channel
  - Rating curve at Section 13089.04 used for 2D HEC-RAS boundary condition
    - Flows range from 0 to 2,740 cfs, and resulting WSE is used in Rating Curve
- 2D HEC-RAS Line E Inlet
  - Inflow hydrograph from Node 130
  - Inflow location is located at the spillway, Q_{100} = 2,675 cfs to simplify modeling
  - Rating Curve at Section 13089.04

H:\2023\23-0008\GIS\Drainage\PDF Figures\2025 PDR - ARC PRO CONVERSIONS\FIGURE 12 BOUNDARY CONDITIONS 3-2025.aprx; Map created 19 Mar 2025

FIGURE 12 - BOUNDARY CONDITIONS

MDP LINE E

FOR MORE DETAILS ON BOUNDARY CONDITIONS PLEASE SEE HEC-RAS EXHIBITS

ALBERT A. WEBB ASSOCIATES

- Low Flow
    - Several flow profiles, flows range from 0 cfs to 36 cfs to simulate typical operations.

This study includes three different HEC-RAS models, with each model having different boundary conditions. Starting upstream, the existing and proposed 2D HEC-RAS inlet model uses an inflow hydrograph for the MDP Line E. The inflow hydrograph is based on the updated hydrology at Node 130. For the existing condition, the downstream boundary is the normal depth of the existing flowline at the end of the mesh. In the proposed 2D HEC-RAS inlet model, the downstream boundary condition is a rating curve based on the MDP Line E 1D HEC-RAS model, run with different flow rates to establish comprehensive flow and WSE profiles. See ***Appendix D*** for HEC-RAS exhibits and results.

The second HEC-RAS model of Line E channel is a 1D HEC-RAS model within the limits shown in ***Figure 12***. The upstream boundary is a normal depth with a slope of 0.001. At the Confluence Basin, the two segments of MDP Line E meet at a WSE of 1456.10 ft. The downstream boundary condition is the San Jacinto River floodplain with an elevation of 1452.93 ft. See ***Appendix D*** for HEC-RAS exhibits and results.

The third HEC-RAS model for Line E is a low-flow analysis looking at the effects of pumping the 100-year dead storage from the Confluence Basin and the SJCCSP onsite basin of a flowrate of 36 cfs for 72 hours. The analysis also looked at a 5 cfs interval to the 100-year max of 36 cfs. The interval flow rates are intended to show how lower storm events will impact the downstream. North of the MWD right of way is an existing open channel that will be concreted (in the proposed condition) when parallel to the MWD right of way. This existing channel alignment is where the future MDP Line Z is slated to be constructed. This existing channel conveys low flows northerly to an existing 60-inch culvert at Ramona Expressway. It should be noted that the limiting facility is the existing 60-inch RCP that crosses Ramona Expressway, due to the culvert being nearly flat (slope). Webb surveyed the city-maintained 60-inch culvert and surrounding area to model the downstream correctly. See ***Appendix D*** for HEC-RAS exhibits and results.

4.1.2 Model Domain and 2D Grid

The model domains for the existing and proposed inlets have the same domain and inflow location, as shown in ***Table 3***. The range of adaptive 2D grid sizes and the total number of cells are also provided. Please refer to the existing and proposed work maps in **Appendix D**.

Table 3– Model Domains

	Adaptive 2D Face Area	Mesh Properties	
	avg-min-max [ft^2]	Dx-Dy	cells
EXISTING INLET	97 - 2 - 186	10 -10	147,655
PROPOSED INLET	97 - 2 - 186	10 - 10	147,554
LOW FLOW	219 – 19 - 396	15 - 15	40,352

4.1.3 Topology

The existing condition topology is based on two different areal topographic maps. See **Appendix D** for signed areal topographic maps used in the HEC-RAS modeling and used in design. The topology has a vertical accuracy of 1-foot. For critical design elements such as the Casa Loma Barrel No. 1, surveyors have completed field surveys to verify the elevations used for design.

4.1.4 Manning's "n" Value

The Manning's roughness coefficient ("n") is used to calculate flow in open channels. Higher "n" values represent rougher conduits with higher friction. The Manning's "n" values used in this study are summarized in ***Table 4***.

Table 4 – Roughness Coefficients Used in this Study

Manning's Roughness Coefficient, "n"	Roughness Description
n = 0.013	Reinforced concrete pipe (RCP)
n = 0.014	Reinforced concrete boxes (RCBs)
n = 0.020	Bare earth channel with no vegetation
n = 0.030	Minimum vegetation density within channel
n = 0.043	One-quarter ton riprap (Class V)
n = 0.044	Three-eighths ton riprap (Class VI)
n = 0.046	One ton riprap (Class VIII)
n = 0.015 to 0.032	Low flow channel assuming no maintenance and moderate to very heavy vegetation at the inlet (2D HEC-RAS models)

Source: RCFC&WCD, May 2023 *Draft Hydraulic Manual.*

4.1.5 Model Time Step

The modeling of the inlet of Line E used an adaptive step with a computational interval of 5 seconds, and in this case, the Courant Methodology was utilized. A computational interval of 1 second was used for the Low Flow outlet scenario so this model does not utilize the Courant Methodology. ***Table 5*** below outlines the time steps each 2D HEC-RAS model utilized. It should be noted that this is not relevant to 1D HEC-RAS and WSPG models.

Table 5 – Model Time Steps

Model	Computational Interval [sec]	Adaptive Time Step [sec]		Time Steps		
		Max	Min	Min Doubling	Max Doubling	Max Halving
EXISTING INLET[(a)]	-	4	1	1	2 (20 sec)	5 (0.16 sec)
PROPOSED INLET[(a)]	-	4	1	1	2 (20 sec)	5 (0.16 sec)
LOW FLOW	1	-	-	-	-	-

Notes:
(a) Courant Methodology

4.1.6 Model Error

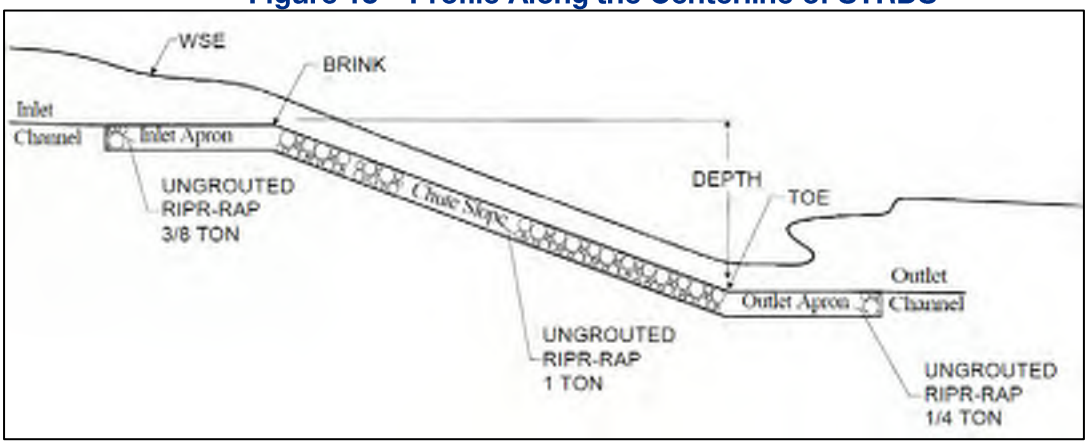
The percent error for the 2D HEC-RAS model is shown below in ***Table 6***. The percent error is calculated on the model's stability and ability to converge to an answer. The modeling error is reasonable and due to the topography, some volume will remain within the model domain.

Table 6– 2D HEC-RAS Model Error

Model	Percent Error	Mass Balance [acre-ft]	
		In	Out
EXISTING INLET	.000745	946.6	921.8
PROPOSED INLET	.00239	946.6	929.3
LOW FLOW[(a)]	.0001 to .0012	27.7 to 152.2	25.3 to 148.3

[(a)]The Low Flow model consists of several pumping regimes

4.2 Modeled Project Design Features



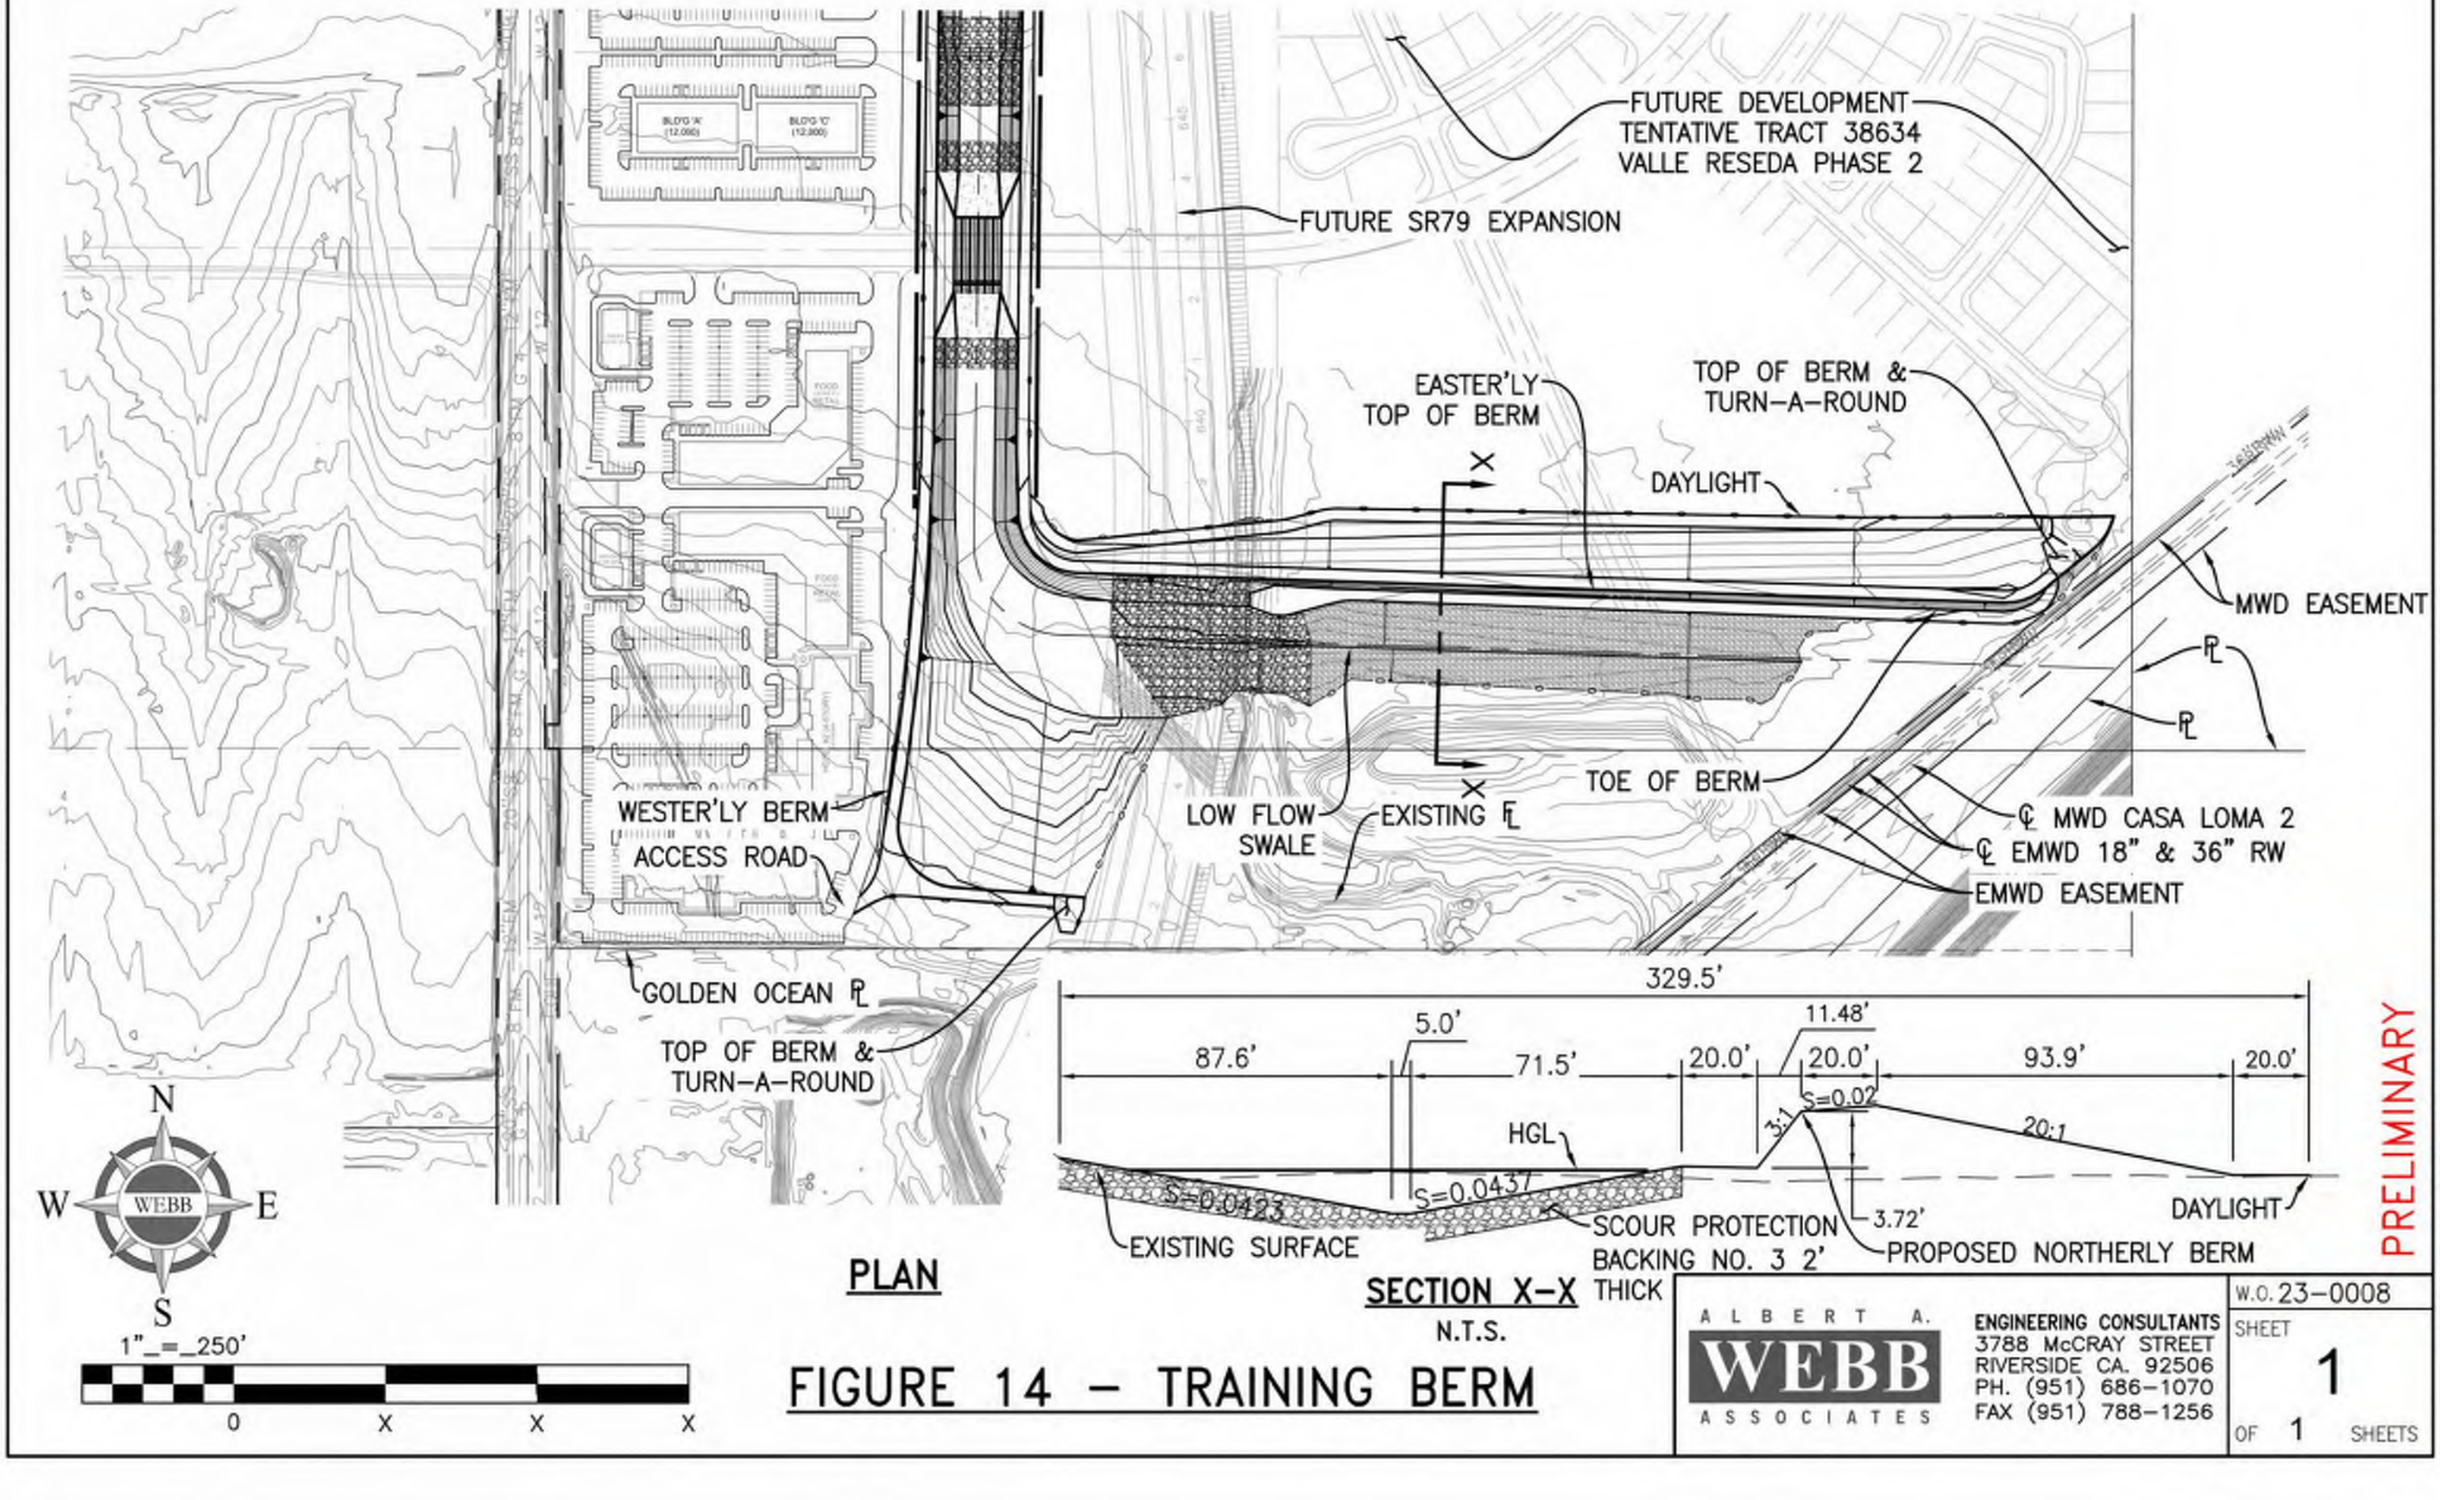
4.2.1 Freeboard

The draft RCFC&WCD Hydraulic Design Manual states that a subcritical channel needs a minimum of 1-foot of freeboard for a subcritical earthen channel. The Froude numbers within the proposed earthen channel sections range from 0.26 to 0.77. At the brink of the drop structures (see ***Figure 13***), the Froude number is 1. At the end of the outlet apron of each drop structure, the Froude number is less than 0.5. In the concrete portion of Line E, the typical Froude number is around 1. The training berms are intended to be conservatively designed with 2-feet of freeboard.

4.2.2 Drop Structures

The original MDP assumed the use of Turf Reinforcement Mat (TRM) for lining the Line E channel as protection against velocity-induced scour. However, RCFC&WCD has since excluded the use of TRM in MDP facilities. Therefore, the design of Line E will instead use Sloped Trapezoidal Rock Drop Structures (STRDS) to reduce channel velocities within the proposed earthen Line E channel.

Figure 13 – Profile Along the Centerline of STRDS



A total of five STRDS are proposed for Line E (**Figure 13**). The upstream and downstream rock-lined channel lengths establish the normal depth (aka steady flow). The downstream length also considers the hydraulic jump length and to be conservative, this study applied a 1.5 safety factor to the apron length.

HEC-RAS was then used to size the STRDS riprap and the sizes of the upstream and downstream ungrouted riprap aprons. The HEC-RAS results are discussed in *Section 4.3*. All riprap in this study is assumed to be ungrouted. Manning's "n" values for the riprap sizes are shown in ***Table 4***. The 3/8-ton riprap will be used in the upstream section of the STRDS, which induces normal depth velocity for the approach. Then, flows drop down inducing critical depth. One-ton riprap is used on the slope where the fastest velocity occurs, and at the end of the grade break, one-quarter ton riprap is used for a slower velocity and returns to normal depth at the end of the downstream apron.

4.2.3 Training Berms

Training berms are proposed to direct flows from the San Jacinto Reservoir Spillway and the sheet flows from the south/southwest into the proposed Line E channel. The Project will have no direct connection to the San Jacinto Reservoir Spillway. The placement of the training berms allows avoidance of MWD Casa Loma Barrel No. 2 easement and EMWD pipeline easement which are located at the end of the easterly training berm (***Figure 14***). Based on the coordination with the City of San Jacinto, the training berm is not considered a levee because the WSE is within 1± foot of the dry side of the Training Berm. In addition, the City of San Jacinto approved a technical memorandum on the hydraulics of MDP Line E Inlet, see **Appendix F**.

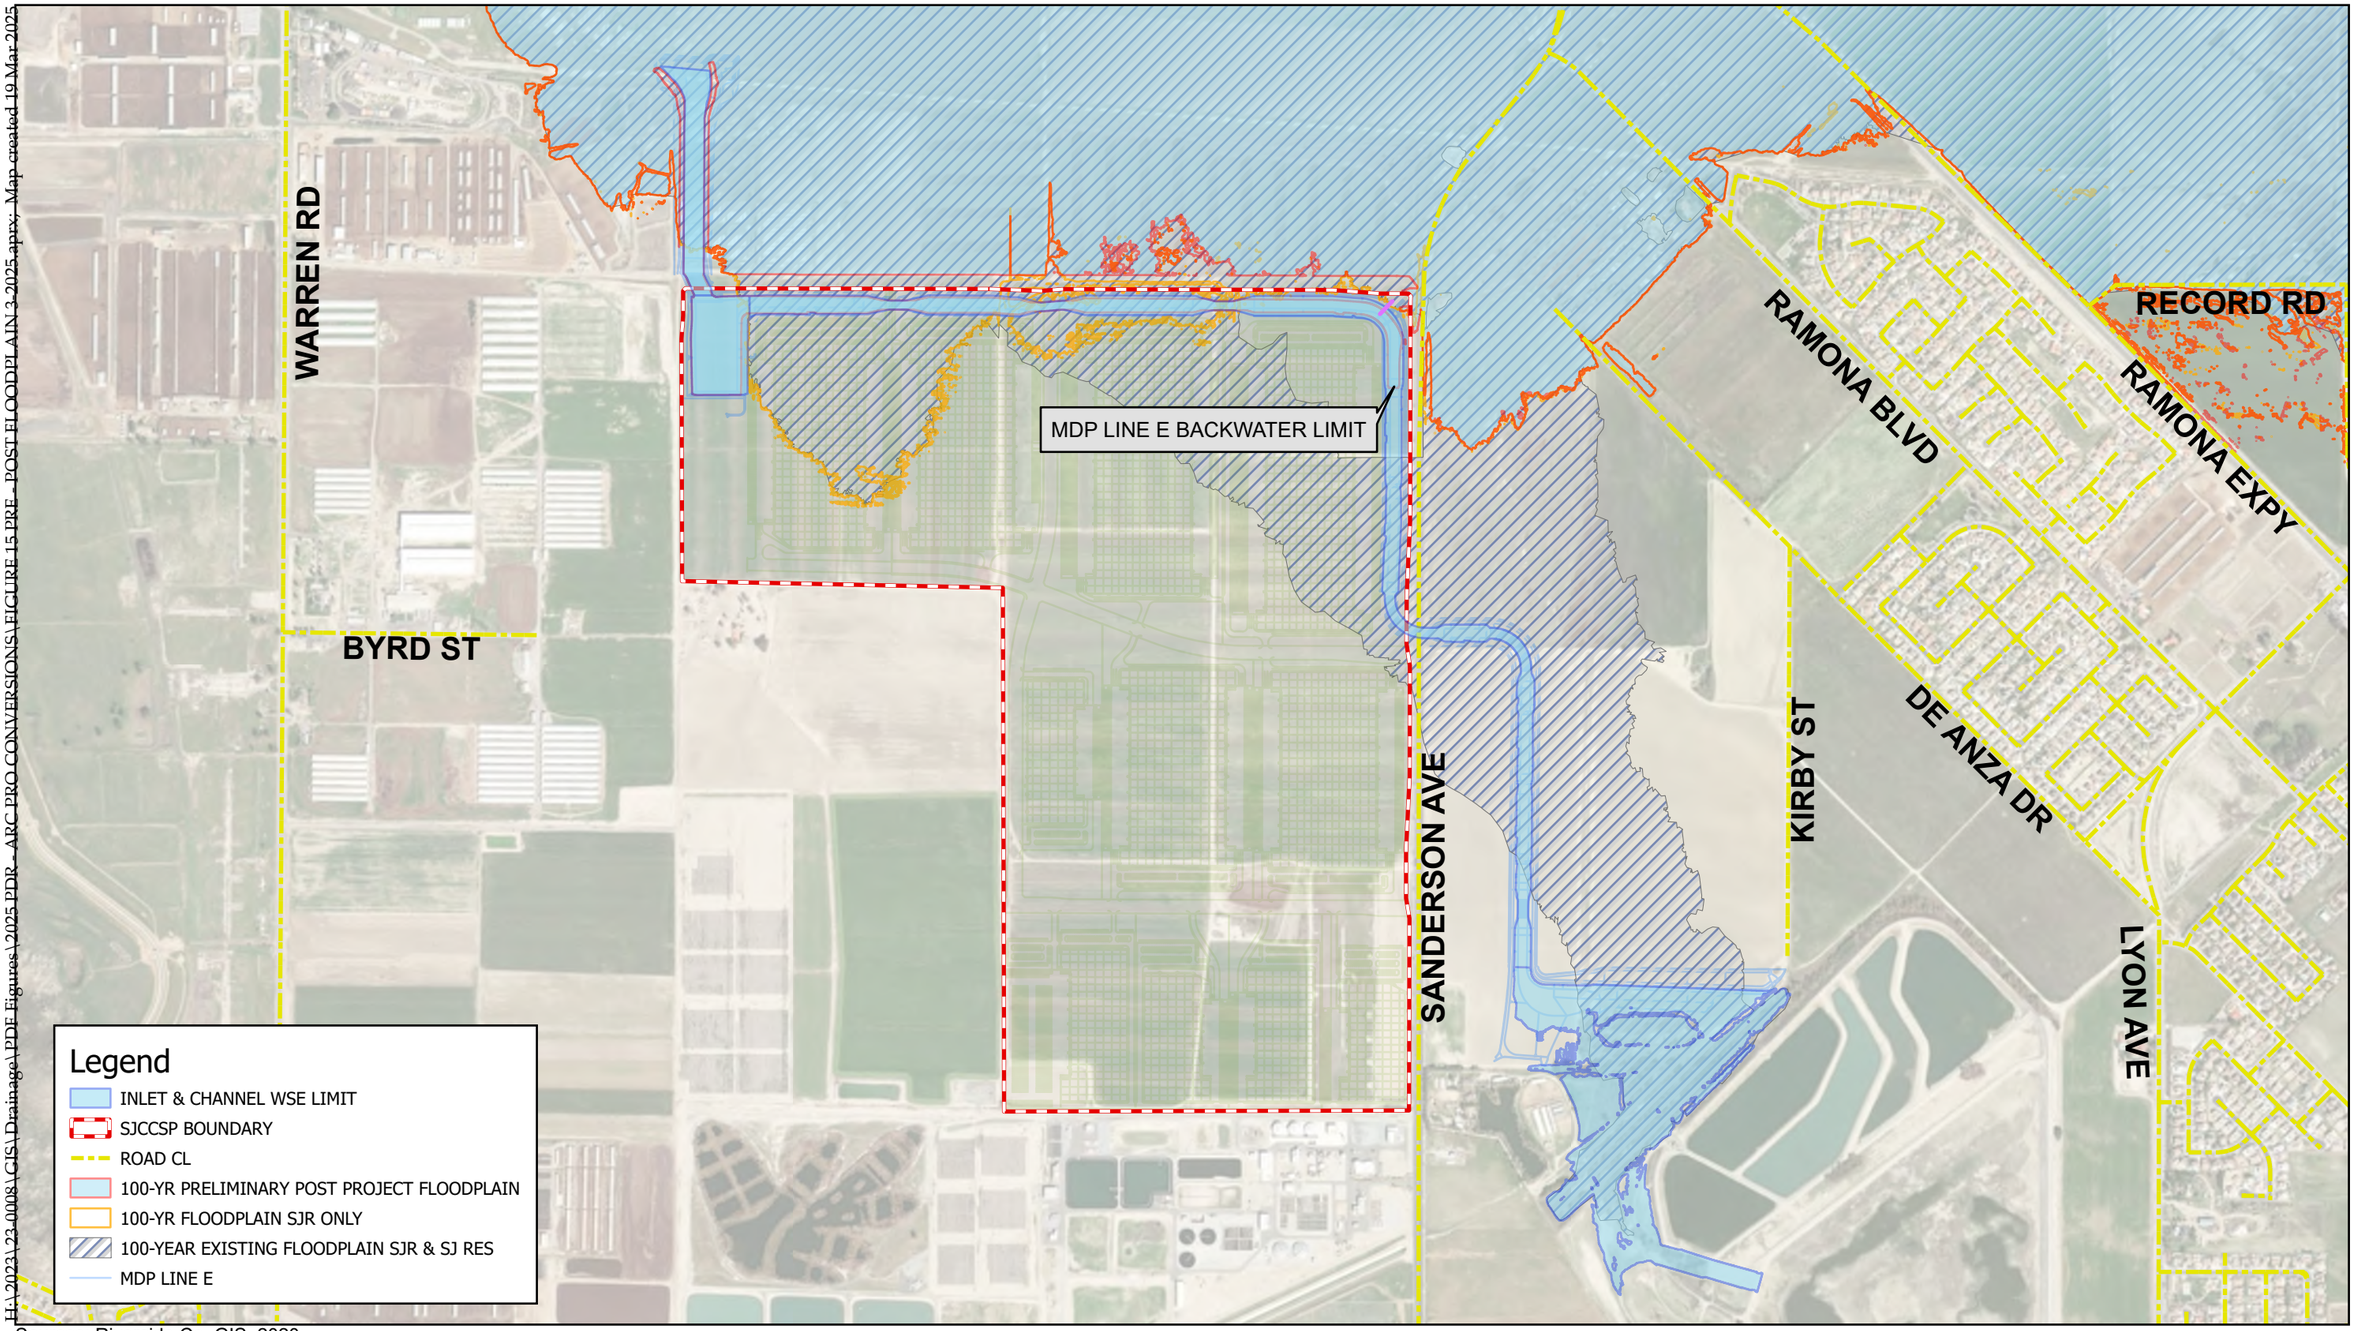
2D HEC-RAS modeling is used to demonstrate that pre- and post-project velocities will be essentially equal over the EMWD and MWD easements and the existing cover over the EMWD and MWD pipes will not be scoured. The pre-project (existing condition) water surface elevations and velocities are shown in **Appendix D** 2D HEC-RAS Inlet Existing Model and proposed post-project water surface elevations and velocities are shown in **Appendix D** 2D HEC-RAS Inlet Proposed Model. Modeling results indicate slow velocities and shallow depths in the 100-Year event scenario. However, where velocities exceed 6 fps, the slope of the training berm will be armored with riprap or a cutoff wall to protect against scour – the specifics of which will be determined in the final design. Modeling results of the 2D HEC-RAS analysis are in **Appendix D**. The 100-Year floodplain limits within the Line E footprint are shown in ***Figure 15***.

The placement of the training berms was chosen to avoid disturbing the riparian habitat that is in the area below the spillway. Indeed, the training berms are placed an additional 50 to 100 feet from the riparian habitat to account for temporary construction impacts that might occur from building the berms.



4.2.4 Scour Potential

HEC-RAS was used to model flows in the following three scenarios:

- To assess the highest scour potential conditions, such as in a freshly excavated bare earth unvegetated channel, an “n” value of 0.02 was used. All of the proposed scour mitigation measures will be designed using n = 0.02.
- To assess the post-project condition with a vegetated channel of minimal vegetation density, an “n” value of 0.03 was used, and n = 0.04 was used to represent flows in a vegetated channel with maximum vegetation density. It should be noted that a “n” value of 0.03 was used to plot the HGL on the long plot in **Appendix A**.

4.2.5 Onsite Basin, Confluence Basin, and Pump Station

The SJCCSP proposes an “Onsite Basin” to capture onsite stormwater and nuisance flows, which works with the proposed MDP Confluence Basin and both basins will be pumped out by a proposed pump station to be located on the SJCCSP property, which will discharge flows into a downstream segment of Line E (***Figure 16***).

H:\2023\23-0008\GIS\Drainage\PDF Figures\2025 PDR - ARC PRO CONVERSIONS\FIGURE 15 PRE - POST FLOODPLAIN 3-2025.aprx; Map created 19 Mar 2025

Sources: Riverside Co. GIS, 2020;
USDA NAIP, 2016.

FIGURE 15 - EXISTING FLOODPLAIN & PRELIMINARY POST PROJECT FLOODPLAIN

MDP LINE E

ALBERT A. WEBB ASSOCIATES

Onsite Basin

The Onsite Basin that is proposed for the SJCCSP property is designed to mitigate the effects of hydromodification that the SJCCSP project poses to areas downstream. Flows will be released from the Onsite Basin via pumps, at a rate no greater than 110% of the pre-development runoff condition's 2-year, 24-hour peak flow rate. Per the city water quality requirements the Onsite Basin dimensions and capacity are not set by this requirement, but rather they were set as a result of the storm drain invert elevations running from the southernmost portion of the SJCCSP site. Under the spillway elevation, the Onsite Basin can hold roughly 145 acre-feet (47.3 million gallons). A 20-foot-wide maintenance access road is provided along the top perimeter of the entire basin. Please refer to the SJCCSP Hydrology and Hydraulics Report prepared by WEBB for details on the onsite storm drain system.

MDP Confluence Basin

The MDP includes a Confluence Basin at the downstream end of the earthen portion of Line E. The basin is earthen with 4:1 side slopes. The RCB outlet of the of Confluence Basin is 4.4± feet higher than the bottom of the basin (1446.50-feet amsl basin bottom). The Confluence Basin has 57± acre-feet capacity over an area of 6.25 acres, with 72-hour drawdown. To pump out the dead storage, the basin parcel includes a pump station. When entitlement is completed for the SJCCSP, the proposed Confluence Basin will be dedicated as its own parcel within the SJCCSP, the parcel will be owned by the City of San Jacinto. The pump station will be located on the Confluence Basin parcel.

Pump Station

A pump station is proposed on the SJCCSP property that will house pumps to drain both the Onsite Basin and the Confluence Basin back into Line E downstream of the basins (***Figure 16***). ***Table 7*** summarizes the pumps that would be required to pump the dead storage volumes from both basins. The primary design criterion for the pumps is to draw down both basins within 72 hours. The total pump station combined flow rate is 36 cfs that will outlet into the RCB's crossing Record Rd. Pump station details will be provided in the final design. The conceptual cost of the pump station is approximately $9.1 million.

Downstream Perched Channel & Levee Concern

The concrete downstream of Line E from the confluence basin to the northerly MWD right of way is a perched channel. During a review of the PDR RCFC&WCD noted that the City will need to make the determination if this portion of Line E is a leveed channel. The City made the determination in an email dated 11-27-24 where the city determined the channel is not leveed. A copy of the email will be included in **Appendix F**.

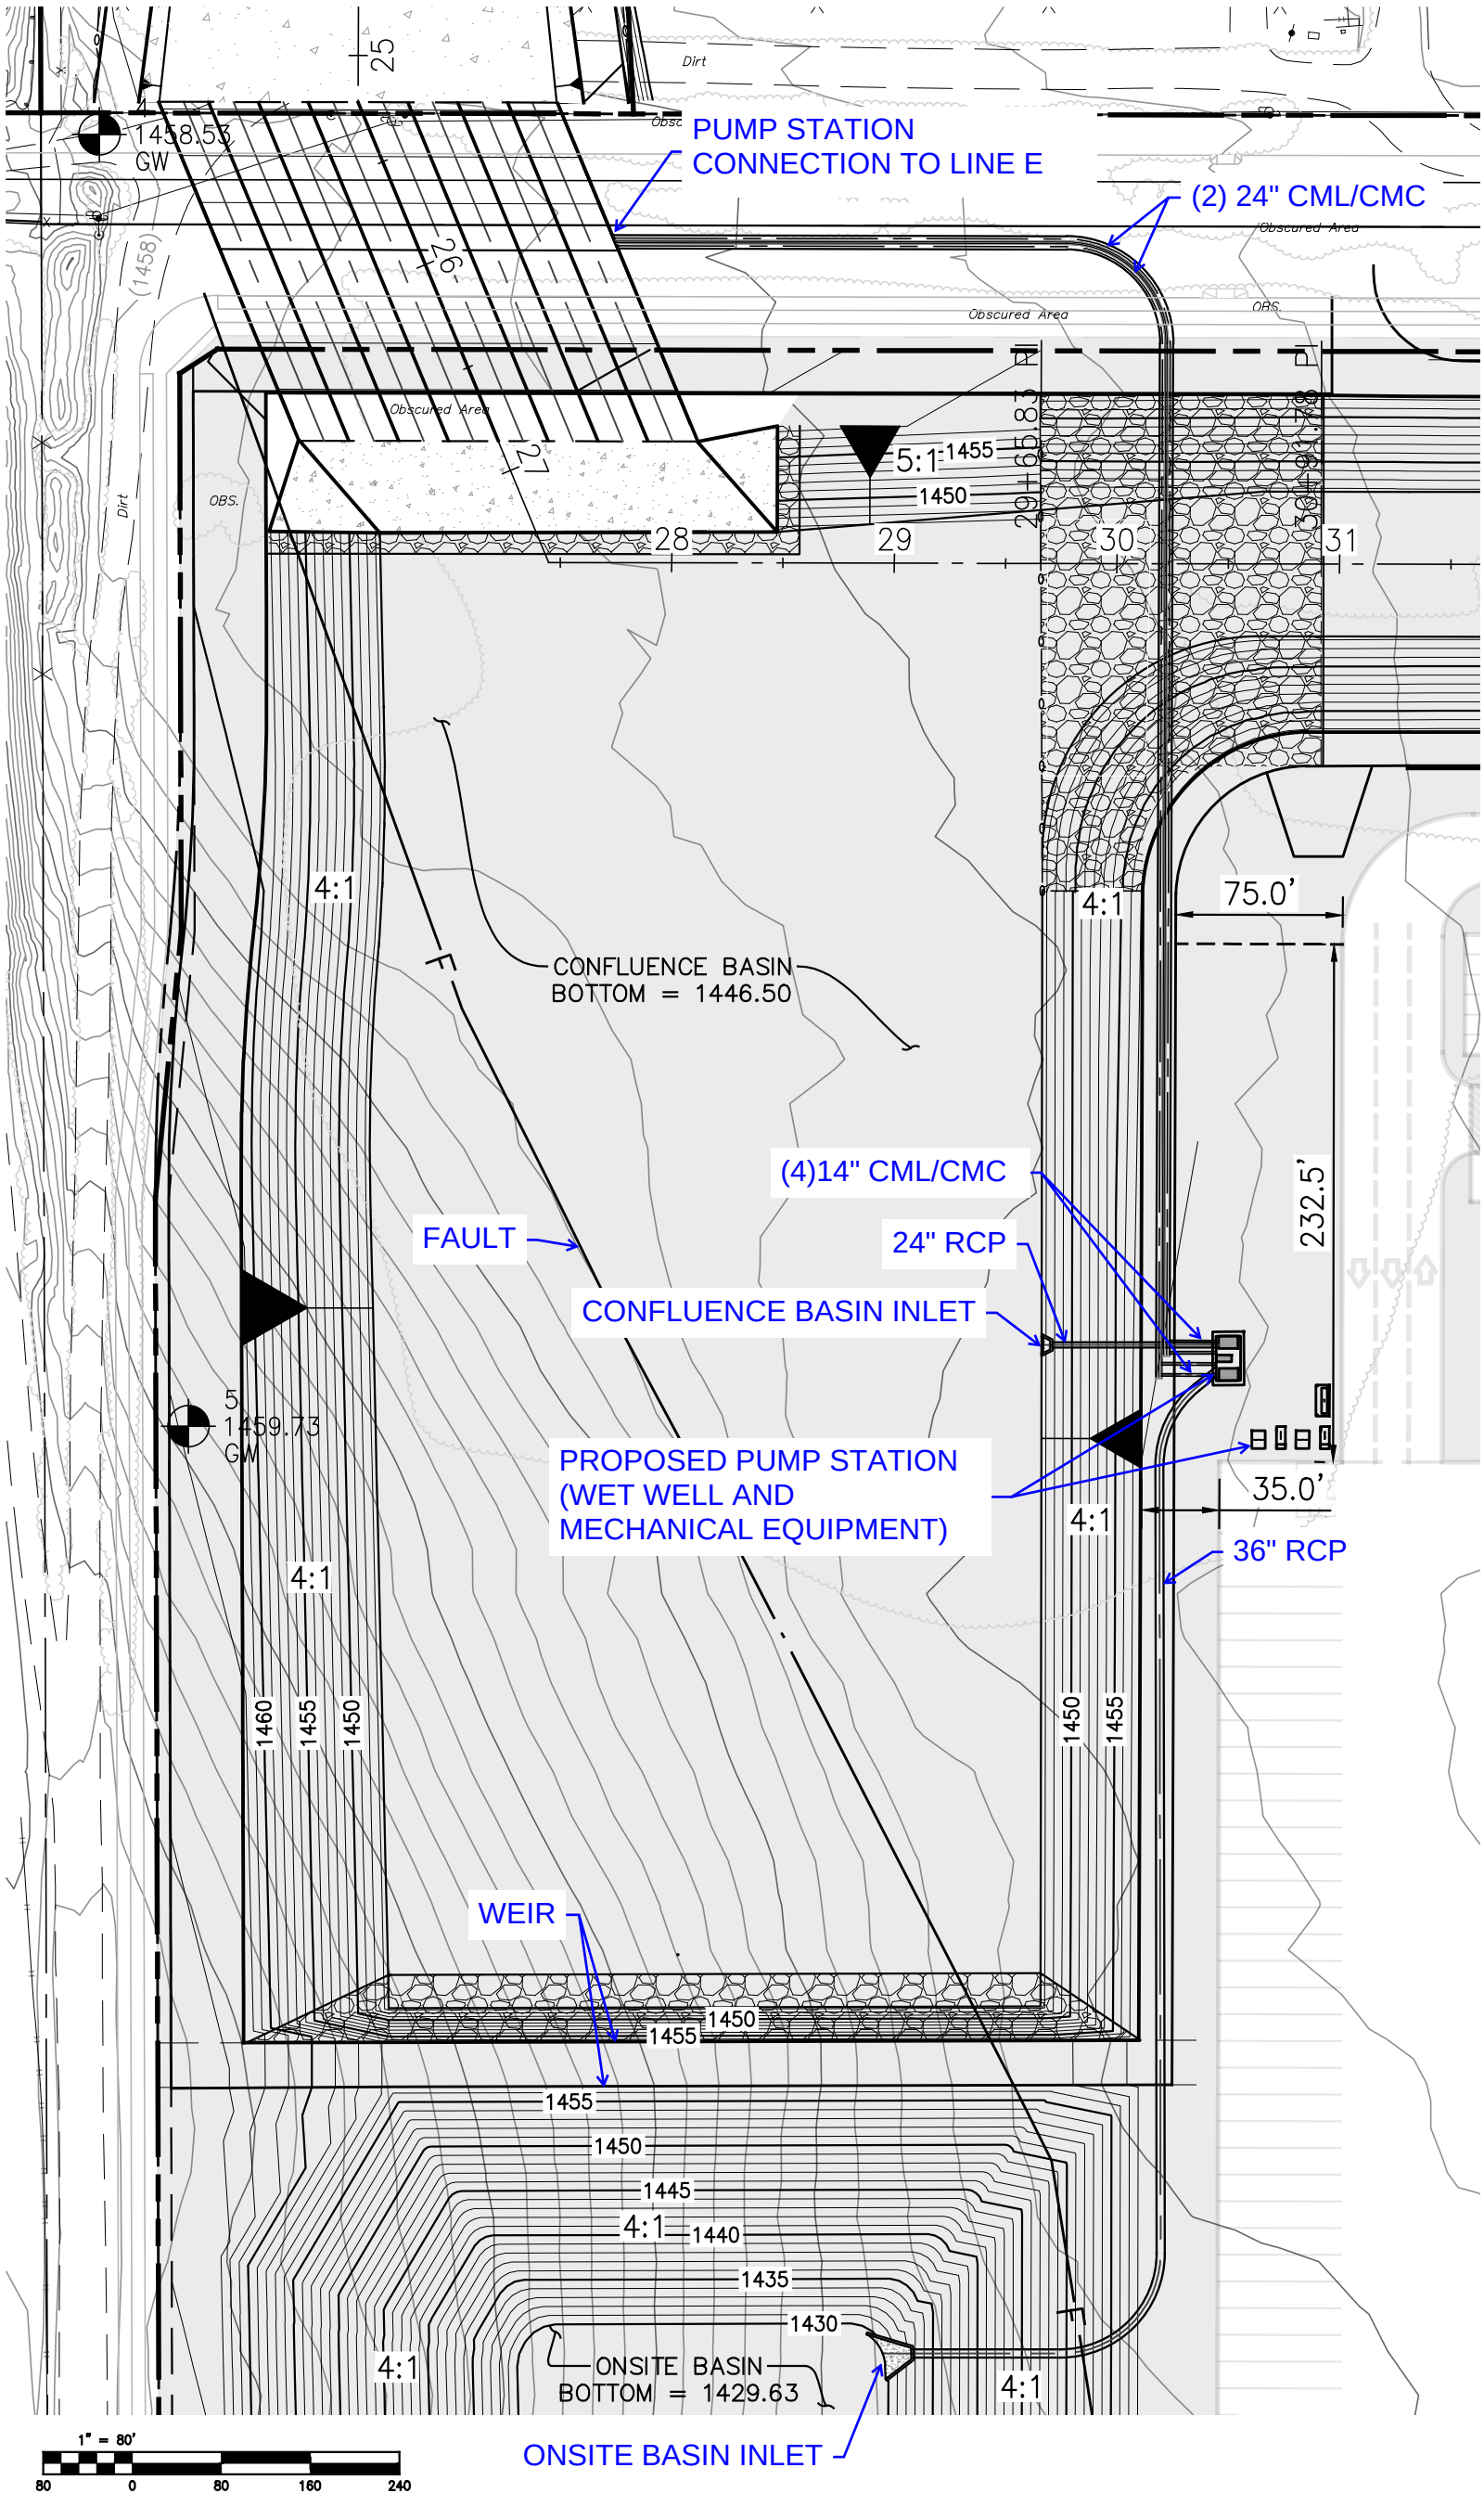


Table 7 -Basin's & Pump Station Details

4.3 Hydraulic Model Results

The results of the hydraulic modeling suggest that post-project flow conditions approximate existing pre-project flow conditions through the MWD and EMWD rights-of-way near the San Jacinto Reservoir Spillway.

In addition, model results suggest the proposed Line E channel has sufficient capacity when an "n" value of 0.04 is applied (i.e., maximum vegetation density) while also sufficiently designed for no scour occurring at the "n" value of 0.03 (i.e., minimum vegetation density).

The velocity profiles along Line E depend on the modeling method used. Both WSPG and HEC-RAS produce similar results for slow and steady flow (see **Appendix A**, Long Plot, Sheets 2 & 3). However, as the flow transitions to unsteady conditions, the models begin to diverge.

This divergence is particularly evident at the STRDS drop structures, where WSPG struggles to accurately compute energy dissipation. WSPG predicts a high-energy hydraulic jump (as shown on Sheet 5 of the Long Plot), while HEC-RAS models a submerged hydraulic jump. The submerged jump is expected due to the downstream water surface elevation being higher than the upstream brink elevation.

Additionally, the Long Plot shows that approach velocities calculated by WSPG are approximately ±2 fps higher than those from HEC-RAS. This suggests that the approach apron in WSPG simulations would, in some cases, experience increased velocities.

Furthermore, the proposed drop structures (STRDS) reduce the 100-Year maximum channel velocities effectively. Model results show the same hydraulics occur downstream of and upstream of each drop structure. Because the net change in flow rates from the upstream and downstream areas of each drop structure is zero, scour is mitigated, and capacity maintained in the proposed channel. The design target velocity is 4 fps for the unvegetated channel and 4 to 6 fps for the vegetated channel. The proposed design has either concrete or ungrouted riprap armor in all locations where velocities are more than 6 fps. Indeed, the modeled velocities for the segment of the proposed Line E channel within the SJCCSP are 6 fps and less, (at the approach of one drop structure the approach velocity reaches 7 fps). Where velocities exceed 4 fps and are below 6 fps, hydroseed will be used for erosion control (refer to **Appendix E** for hydroseed mix provided by RFC&WCD).

Likewise, the low flow model results for pumping out the Confluence Basin and Onsite Basin suggest the downstream (offsite) system is not impacted during pumping out of the dead storage. Based on the model results, the (off-site) low flow channel has a capacity of 75 cfs before spilling over. However, the city-maintained 60" RCP culvert crossing Ramona Expressway, is undersized. Webb surveyed the existing culvert to include the actual culvert slope and length for the Low Flow Analysis, see **Appendix D** for result exhibits.

On the other hand, where the concrete-lined portion of Line E outlets to the existing downstream/offsite low flow channel to the north of the Project, as shown in ***Figure 11***, the velocity increases to more than existing. In addition, if the San Jacinto Reservoir overflows, but the San Jacinto River is not overflowing and flooding the area, the functionality of the 60-inch diameter RCP culvert under Ramona Expressway that drains the low flow channel to which the Project drains, is absolutely critical to successful drainage of the study area. However, that capacity is limited and by the time the peak flow from Line E arrives to the culvert at Ramona Expressway, the area will already be inundated. Detailed analysis of offsite downstream properties is not included in this study.

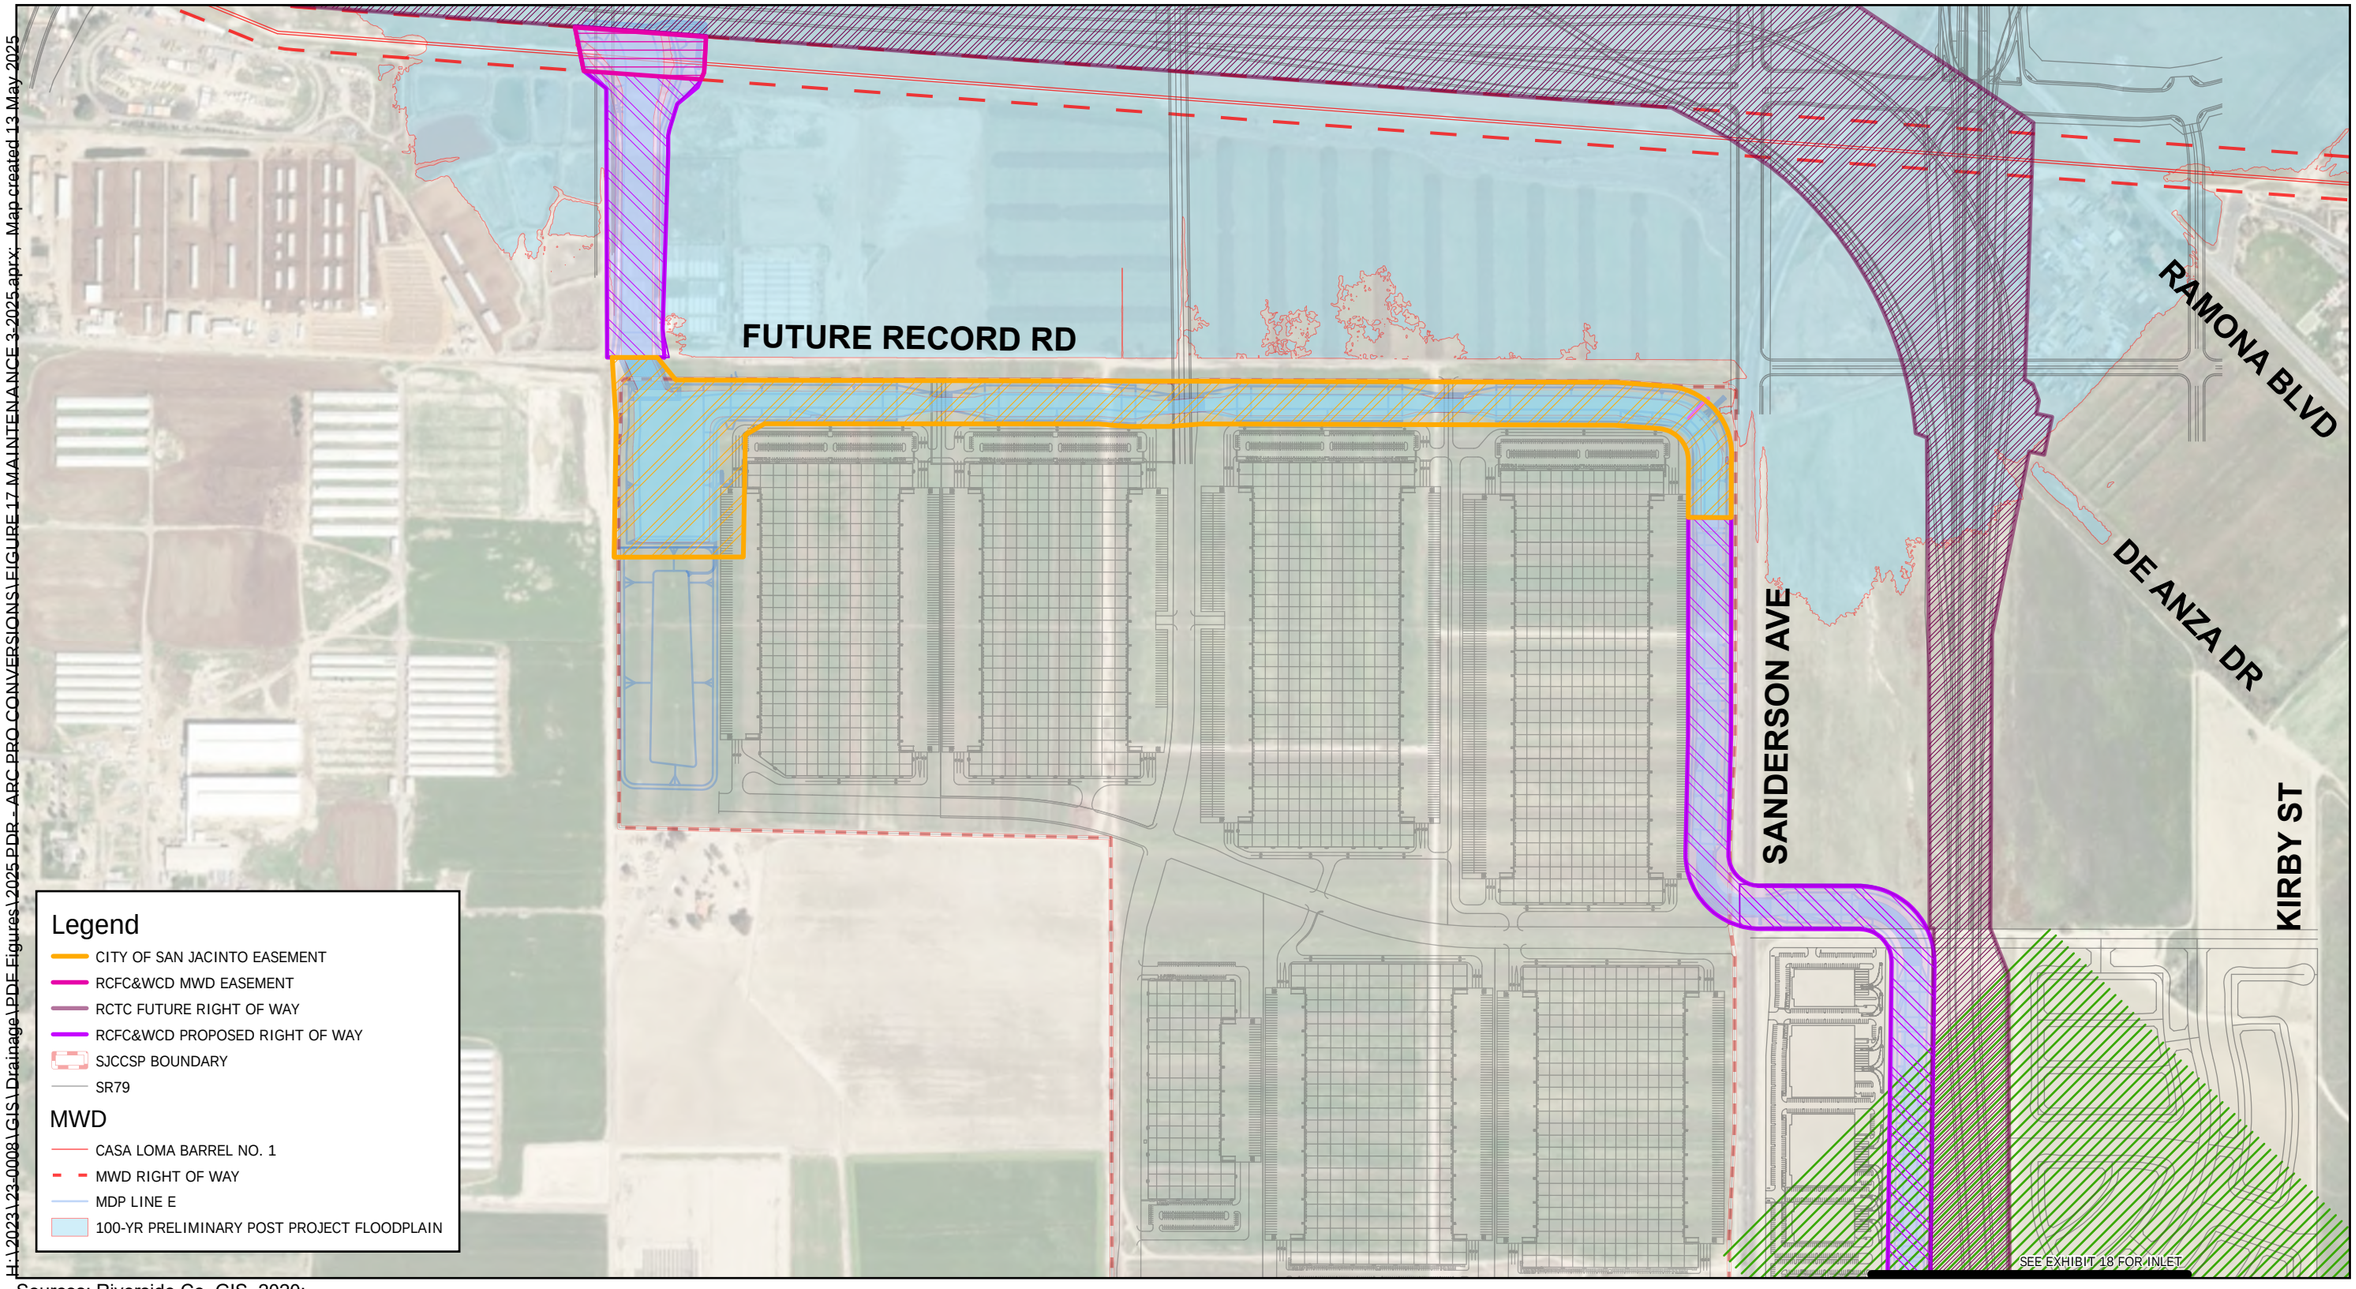
Section 5 Right of Way & Maintenance

Maintenance obligations are currently expected to be assigned as follows, overall maintenance and easement areas are defined in ***Figure 17*** MDP Line E Lower Reach (outlet) and ***Figure 18*** MDP Line E Upper Reach (Inlet):

- Riverside County Flood Control & Water Conservation District

  Project Components

  RCFC&WCD would maintain Training Berms & inlet line and grade via a drainage easement and slope easement, Line E channel (with 20-foot access roads) and owned right of way (includes Line E downstream of confluence basin to MWD right of way and starting from station 80+95 per the Long Plot in **Appendix A** (from station 80+95 to 82+25 access road transitions from a 15' to 20'), RCBs, and drop structures within Right of Way, Line E and over the Casa Loma Barrel No. 1 & MWD right-of-way via a maintenance easement, geotechnical and structural measures to protect Casa Loma Barrel No 1.



- City of San Jacinto

  Project Components

  City of San Jacinto would maintain the Line E channel segment (with 15-foot access roads) within the SJCCSP boundary via a drainage easement, onsite water quality basin, Confluence Basin, and Pump Station. The city-maintained segment of Line E ends at the downstream end of the first drop structure, which is station 80+95 per the Long Plot in **Appendix A**.

It should be noted that MWD will not maintain structural (structural protection of Casa Loma No. 1) or geotechnical (lightweight fill) design components of this project.

Section 6 Recommendations

Based on the analysis presented herein, it is recommended that the City and RCFC&WCD approve the proposed modifications to the MDP Line E alignment. It is also recommended that Line V be removed because this drainage area will now be accommodated by an onsite system on the SJCCSP site. MDP Line E-2 will have to cross MWD Casa Loma Barrel No. 2 to connect to MDP Line E. Feasibility of MDP Line E-2 is not within the scope of this project.

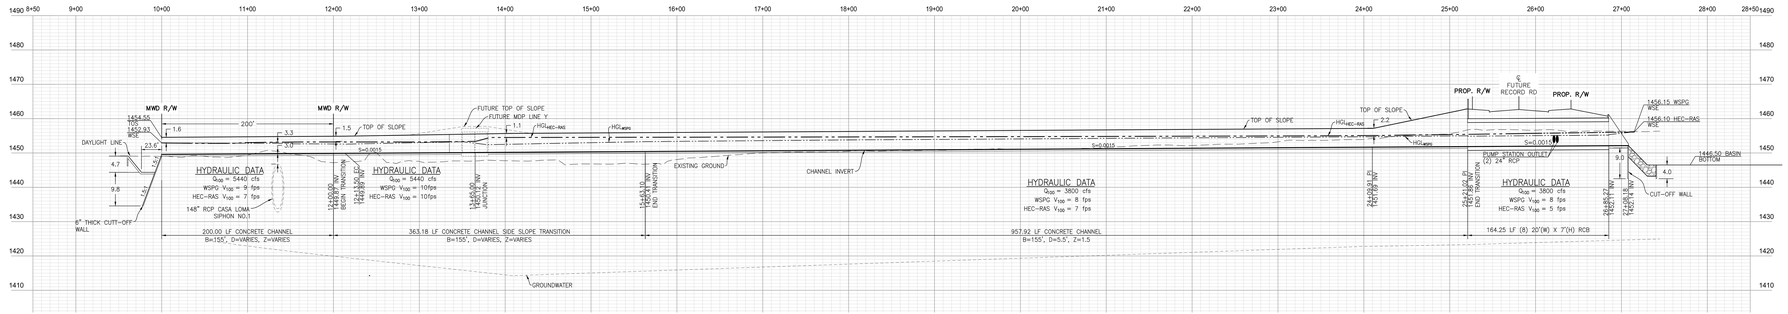
Final design of the Line E system will take place in conjunction with the development of the SJCCSP, *Section 7* outlines the final design items. Other future projects will design downstream MDP facilities, Line G and Line E-2 as well as other backbone facilities throughout the City. It should also be noted that the connection of MDP Line E to the San Jacinto Spillway while crossing Casa Loma Barrel No. 2 and the San Diego Pipeline, is planned as a future project. It is recommended that the flow rates established in this report be utilized for the Final Design of Line E and Line G.

Section 7 Next Steps

Following the approval of the PDR the following items will need to be developed, coordinated, or designed in the final design stage of MDP Line E development. The following list includes long lead items but is not exhaustive of all design elements.

- MWD
  - Finalize structural design for Casa Loma Barrel No. 1 for final design
  - Finalize geotechnical analysis for final design
  - Casa Loma Barrel No. 1 blowoff manhole structural design to proposed grade
  - Lightweight fill extents and protection extents
  - Obtain final MWD approval on structural and geotechnical construction plans and reports
  - Easement for construction and RCFC&WCD to maintain Line E from MWD's Real Estate Group

- City of San Jacinto
  - Onsite & Confluence Basin
    - Size, freeboard, weir design, and scour protection
  - Pump Station
    - Final pump selection, mechanical selection, electrical plan, Structural design of wet well
  - Easement for the City of San Jacinto to maintain Line E



- RCFC&WCD
  - Obtain RCFC&WCD approval of freeboard for MDP Line E for areas outside of SJCCSP boundary and within adjacent developments to verify offsite drainage
  - 20' access roads within the SJCCSP boundary
  - Non-standard RCB structural design, transition structures structural design
  - Low flow channel per RCFC&WCD CH324, extents and design to be determined
  - Right of Way Acquisition and Easements for Line E Maintenance (including MWD)
  - Additional groundwater investigations near inlet
  - Construction phasing
- Environmental
  - Complete the CEQA process with the City of San Jacinto and obtain regulatory permits for the construction and maintenance of Line E.
  - City of San Jacinto, as CEQA lead agency adopts Addendum
  - RCFC&WCD as a CEQA-responsible agency makes Responsible Agency Findings
  - Implement mitigation measures identified in the Addendum's Clarified Mitigation Monitoring and Reporting Program (Clarified MMRP)

Haley,

There were no comments from our Engineering disciplines at this time. I am hopeful this email will suffice.

Subject: RE: Line E - MWD Settlement & Structural Review (MS212, 2023-0008)

Thank you Ken, we appreciate your quick review.

Flood Control is looking for confirmation that MWD finds the preliminary/geotechnical package acceptable, and that we have approval to proceed with the final engineering plans and right-of-way. Are you able to provide us with a letter to provide to Flood Control with our submittal package? If not, I will include your email with our submittal.

Our preliminary design report will not include the final design items you've mentioned below, however we will begin working on those items once we receive approval from Flood Control on the PDR.

Hi Ken,

Please find the enclosed revised structural and geotechnical report for the Line E project for your review: MWD PC3. The package includes the following:

- Responses to comments on the Geotechnical and Structural reports received on 12/5/2024.
- Updated Geotechnical report with settlement analysis.
- Updated Structural Report.

We anticipate this will satisfy your prior comments, and once approved we will proceed with resubmitting the PDR to the District. Please let us know if you have any questions, and what your turnaround timeframe for review looks like.

Thank you, and have a nice weekend.

San Jacinto Line E Storm Drain
San Jacinto, California

Dear Mr. Hays:

Kleinfelder, Inc. (Kleinfelder) is pleased to present this Geotechnical Investigation Report for the San Jacinto Line E Storm Drain project in San Jacinto, California. This report summarizes the findings of our investigation and presents geotechnical design parameters and recommendations for design and construction of the project.

We appreciate the opportunity to be of service on this project. If you have any questions, comments, or require additional information, please do not hesitate to contact the undersigned.

Sincerely,

1 INTRODUCTION

This report presents the results of our geotechnical investigation for the San Jacinto Line E Storm Drain project in San Jacinto, California. The project location is shown on Figure 1, Site Vicinity Map. The purpose of the investigation was to evaluate surface and subsurface conditions in the area of planned improvements and to provide geotechnical recommendations for earthwork, design and construction considerations.

The conclusions and recommendations presented in this report are based on subsurface conditions encountered at the locations of our field investigation, laboratory testing, and our evaluation of the data. The provisions and requirements outlined in the Limitations section of this report are also an integral part of the development of our conclusions and recommendations.

1.1 PROJECT DESCRIPTION

We understand that the project involves design of an approximate 3-mile storm drain channel to be constructed in the City of San Jacinto. The new storm drain channel will be constructed near the existing ground surface and the majority of the alignment will consist of an earthen channel with a 65-foot base width, heights up to 10 feet, side slopes inclined at 4:1 (Horizontal:Vertical), and several sloped rip-rap drops along the alignment. In addition, several 6 to 8-cell reinforced concrete box (RCB) culverts with cell widths up to 14 feet and cell heights up to 9 feet are planned at existing or proposed roadways along the alignment. Storm water flow is generally south to north and a training berm is proposed on the south end of the alignment. At the northern portion of the alignment the proposed earthen channel terminates at a proposed confluence basin and the remainder of the alignment converts to a concrete channel with a 145-foot base width, height up to 10 feet, and side slopes inclined at 1.5:1 (H:V).

At the northern end of the proposed concrete channel portion, the proposed alignment crosses an existing Metropolitan Water District (MWD) pipeline (Casa Loma Siphon No. 1). We understand this pipeline is an approximately 14.5-foot diameter reinforced concrete pipe. It is proposed to cross the MWD pipeline with a relieving slab (approximately 14-inch thick concrete slab overlying a 6-inch low density polystyrene foam) supported on shallow footings to minimize adding loads to the existing pipeline. Per MWD requirements, we understand the crossing structure is required when cover over their pipe is less than 4 feet. We understand the crossing structure slab will be approximately 203 feet long and 31 feet wide. Footings will be continuous, approximately 10 feet wide, and approximately 7 to 9 feet deep.

1.2 PURPOSE AND SCOPE

The purpose of this study was to investigate and evaluate the surface and subsurface conditions along the proposed project alignment. Field explorations were performed along the alignment to identify potential geologic hazards and provide geotechnical recommendations for design and construction of the project.

The services performed as part of this investigation were provided in general accordance with our proposal dated June 28, 2023. Specifically, our scope of work includes the following:

- A description of the proposed project including a site vicinity map and a site plan showing the locations of the subsurface explorations;
- A discussion of historical and geologic research pertinent to the proposed project;
- A summary of the surficial and subsurface site conditions encountered during our field investigation;
- A discussion of geologic hazards;
- Analysis for liquefaction potential;
- Recommendations for seismic design parameters;
- Analysis for MWD pipeline settlement;
- Recommendations for design and construction of the proposed MWD pipeline crossing;
- Recommendations for site preparation, earthwork, temporary slope inclinations, fill placement, and compaction specifications;
- Recommendations for temporary shoring;
- Recommendations for subgrade preparation and support of storm drain channel;
- Recommendations for pavement structural sections;
- Preliminary evaluation of the corrosion potential of the on-site soils; and
- Appendices including logs of borings and CPTs, laboratory test results, and surface wave measurement results.

Copyright 2025 Kleinfelder

2 BACKGROUND STUDIES

2.1 LITERATURE REVIEW

Geologic and geotechnical literature was reviewed including reports, maps, and other documents prepared by the California Geological Survey (CGS), the U.S. Geological Survey (USGS), and other agencies. We also reviewed maps and preliminary documents pertaining to previous investigations at the site prepared by Leighton and Associates, Schaefer Dixon Associates, and SoCalGeo.

These reports, maps and other documents are listed in Section 8, References. Pertinent findings and information contained within these maps and reports are discussed within the body of this report.

2.2 FIELD RECONNAISSANCE

A field reconnaissance of the site was performed prior to initiation of our subsurface investigation program and following our literature review. The purposes of the field reconnaissance were as follows:

- Visit and observe site conditions at proposed exploration locations;
- Evaluate equipment accessibility for field investigations;
- Document earth materials and geologic conditions present along the alignment and surrounding area; and
- Evaluate features identified during the literature review.

Copyright 2025 Kleinfelder

3 FIELD INVESTIGATION

The field investigation activities for this project commenced with utility clearance for proposed boring and Cone Penetrometer Tests (CPT) explorations. Following utility clearance, the field investigation included drilling and sampling of 19 hollow-stem auger borings and performing 2 CPTs. Discussions of the field investigation program including utility clearances, exploration methods and sampling methods are provided below.

3.1 UTILITY CLEARANCES

Prior to beginning the field exploration program, Underground Service Alert (USA) was contacted to identify potential conflicts between the planned exploration locations and existing, documented, underground utilities. Ground penetrating radar was also performed for utility clearances at the exploration locations. Furthermore, the boring and CPT locations were hand augured generally to 5 feet below the existing ground surface before commencing work.

3.2 FIELD EXPLORATION

The subsurface exploration program included drilling 19 hollow-stem auger borings, performing 2 CPTs, and performing 2 seismic surface wave measurement arrays along the project alignment for geotechnical characterization purposes. The borings were drilled between September 26, 2023 and September 28, 2023. The CPTs were performed on October 11, 2023. The seismic surface wave measurement arrays were performed on September 23, 2024 and September 24, 2024.

In general, the borings were located along the storm drain alignment, with adjustments made in the field as needed to avoid access or utility conflicts. The CPT locations and seismic surface wave measurement arrays were performed in the vicinity of the proposed MWD pipeline crossing. The approximate locations of the exploration locations are shown on Figure 2, Exploration Location Map.

3.3 SOIL BORINGS

For this project, 19 soil borings were drilled using truck-mounted hollow-stem auger drill rigs supplied by 2R Drilling of Chino, California. Hollow-Stem Auger (HSA) drill rigs were equipped with 8-inch outside diameter (O.D.) continuous flight, hollow-stem augers. The auger method was used following the general ASTM guidelines D1452 “Standard Practice for Soil

Copyright 2025 Kleinfelder

Investigation and Sampling by Hollow-Stem Augers." The drilling equipment was selected based on anticipated subsurface conditions and vehicle access. The borings were drilled to a depth of approximately 20 feet below ground surface (bgs), with exception to the borings in the vicinity of the proposed MWD pipeline crossing (B-1 and B-2) and at the southern end of the concrete channel portion of the alignment (B-4), which were drilled to approximately 50 feet bgs. Four (4) of the 19 borings were converted to piezometers (Borings B-6, B-9, B-14, and B-15). The remainder of the borings were backfilled with excess soil cuttings upon completion.

Subsurface conditions encountered in the soil borings were logged by an experienced engineer or geologist, under the review and direction of a licensed Engineering Geologist or Geotechnical Engineer, who also performed the sampling described below. Soils were logged in general accordance with the Unified Soils Classification System. The boring logs are presented in Appendix A, Field Exploration.

3.4 SAMPLING METHODS FOR SOIL BORINGS

Disturbed and relatively undisturbed samples of the subsurface materials were obtained from the borings using Standard Penetration test (SPT) samplers and California-type (CAL) samplers, respectively. The SPT sampler has a 1.375-inch inside diameter and a 2.0-inch outside diameter. The CAL sampler has a 2.42-inch inside diameter and a 3.0-inch outside diameter. Samples were collected in accordance with the general guidelines of ASTM D1586 "Standard Test Method for Penetration Test and Split-Barrel Sampling of Soils."

Samples were driven 18 inches into the soil using a 140-pound automatic hammer falling 30 inches. SPT and CAL samples were obtained at 5-foot intervals alternating between the SPT and the CAL until reaching the boring target depth. Large bulk samples were also obtained within the upper 5 feet from each boring.

The number of blows required to drive the samplers were recorded for each 6-inch penetration interval. The number of blows required to drive the samplers for the last 12 inches, or the interval achieved where higher resistance was encountered, is referred to as the blow count and is noted on the boring logs. The blow counts recorded on the boring logs are recorded in 6-inch intervals. Where the sample was driven less than 12 inches, the number of blows to drive the sample for each 6-inch segment, or portion thereof, is shown on the logs. For example, 50/4" indicates 50 blows to drive the sampler 4 inches to refusal. After the samplers were withdrawn from the test borings, select samples were carefully removed, sealed to reduce moisture loss, and transported to our laboratory for testing.

Copyright 2025 Kleinfelder

3.5 CONE PENETRATION TESTING

Two CPTs were performed in the vicinity of the proposed MWD pipeline crossing because potentially liquefiable soils were anticipated. The CPTs were performed by Kehoe Testing & Engineering, Inc. of Huntington Beach, California using a 30-ton truck rig. The CPTs were advanced to a maximum depth of 100 ft bgs. Upon completion, the CPTs were backfilled with hydrated bentonite chips. The CPT visual plots and data are presented in Appendix A, Field Exploration.

3.6 SURFACE WAVE MEASUREMENT TESTING

Two seismic surface wave measurement arrays were performed in the vicinity of the proposed MWD pipeline crossing to determine shear (S) wave velocity profiles in support of the MWD pipeline settlement analysis. The surface wave measurements were performed by GEOVision of Corona, California. The approximate array locations are shown on Figure 2. A detailed report of the surface wave measurements is presented in Appendix C, Surface Wave Measurements Report.

Copyright 2025 Kleinfelder

4 LABORATORY TESTING

4.1 GEOTECHNICAL TESTING

Laboratory testing was performed on samples obtained from the borings following field exploration. Laboratory tests were performed on drive and bulk soil samples to estimate engineering characteristics of the various earth materials encountered. Selected samples from the borings were tested to evaluate their physical characteristics and engineering properties. The laboratory testing program was formulated with the emphasis on evaluating the density, plasticity, shear strength, and gradation of the soils encountered. Classifications made in the field were modified as appropriate, based on the laboratory test results. The description of the subsurface conditions and classifications presented in the boring logs reflect the changes made as a result of the laboratory tests.

The laboratory index tests, and engineering property tests performed included determination of in-situ moisture content and dry density, wash sieve, sieve & hydrometer analysis, Atterberg limits, direct shear, consolidation testing, expansion index, compaction curve testing, R-Value, and preliminary corrosivity testing including pH, minimum resistivity, sulfate content, and chloride content. Laboratory test results are presented in Appendix B, Laboratory Testing.

5 SITE CONDITIONS

5.1 TOPOGRAPGHY AND DRAINAGE

The project is in the San Jacinto Valley in west Riverside County, about 4 miles northwest of the city of San Jacinto, California. The project site is in an area of farmland on the floodplain on the southwest side of the San Jacinto River, which is channelized in the northern San Jacinto Valley and which drains northwest before turning southwest toward Lake Elsinore. The site is on the west side of the valley below the granitic highlands of the Lakeview Mountains to the west and the San Jacinto Mountains to the east.

5.2 GEOLOGIC SETTING

California is divided into eleven natural geomorphic provinces that are recognized based on geology, landscape or landform, topographic relief, and climate. The project is in the Peninsular Ranges province which extends from the San Gabriel and San Bernardino mountains north of the site southward into lower California, and from the coast eastward to the Colorado Desert (Norris and Webb, 1990).

The Peninsular Ranges are a series of northwest-trending mountain ranges and valleys subparallel to major faults branching from the San Andreas fault system. The Peninsular Ranges are divided into three fault-bounded structural blocks comprised of mostly granitic rocks intruding sedimentary rocks and older metamorphic rocks (Norris and Webb, 1990). The project area is near the north end of the middle (Perris) block.

The north end of the Perris block is bounded by active faults: the Sierra Madre fault on the north, the Elsinore fault on the west, and the San Jacinto fault on the east. The site is in the San Jacinto fault zone (SJFZ) at the east edge of the Perris block.

The northwest-striking SJFZ is a major right-lateral strike-slip fault zone in southern California (Onderdonk et al., 2013). The San Jacinto Valley is a pull-apart basin bounded on the northeast by the Claremont strand of the SJFZ and on the southwestern margin of the valley by the Casa Loma fault strand, two of the many fault strands that make up the SJFZ. Northwest of the site, the Casa Loma fault bounds a 1.5-mile-wide extensional step-over at Mystic Lake (a sag pond), and to the southeast the Casa Loma fault is co-linear with the Clark fault, the primary strand of the central SJFZ (Rockwell et al., 2015). The Casa Loma fault intersects the proposed onsite

Copyright 2025 Kleinfelder

and confluence basins at the north end of the alignment and the proposed Line E inlet at the south end (USGS, 2006).

The proposed alignment lies east of the Casa Loma fault (USGS, 2006), with the exception of the onsite basin, and is within the structural basin part of the San Jacinto Valley between the Casa Loma and Claremont faults. The thickness of valley sediments within the structural basin between the Casa Loma and Claremont faults may exceed 5000 feet, but valley sediments are much thinner west of the Casa Loma fault, reaching maximum depths of about 900 feet (DWR, 2013).

5.3 STATIGRAPHY

The proposed alignment occupies the floodplain of the San Jacinto River and is underlain by alluvium comprised of sandy fluvial deposits and silty to clayey overbank (flood) deposits. Geologic mapping by Morton et al. (2001) shows young alluvial deposits east of the Casa Loma fault scarp and slightly older deposits west of the scarp, which was a barrier to flood deposition. Radiocarbon dates from detrital charcoal samples collected near the alignment for studies of the Casa Loma fault (Schaefer Dixon, 1993; Givler et al., 2022) indicate the fault juxtaposes late Holocene deposits on the east against latest Pleistocene to early Holocene deposits on the west.

Following are brief descriptions of the soil units encountered in our borings. Detailed logs are presented in Appendix A.

5.3.1 Artificial Fill

Artificial fill is present locally along portions of the study area, generally beneath existing roads. The fill overlies native materials and generally consists of a thin veneer of locally-derived sandy silt and silty sand. The fill soils are considered undocumented and are not shown.

5.3.2 Young Alluvium (axial valley floor deposits [Qya])

Holocene-age sandy fluvial deposits and silty to clayey overbank (flood) deposits associated with the San Jacinto River (Morton et al., 2001). Alluvial soils were encountered in borings B-1 through B-19 and primarily consisted of fine silty sand and sandy silt, with lesser amounts of silt, sand, and clayey sand. Boreholes drilled farther from the river channel encountered slightly finer soils, consistent with floodplain deposition. Relative density ranges from predominantly loose to medium dense and stiff to very stiff.

Copyright 2025 Kleinfelder

5.4 FAULTING AND SEISMICITY

5.4.1 Faulting

The project is in seismically active southern California. The project is within the zone of influence for several faults which are considered active or potentially active. An active fault is a fault that has experienced seismic activity during historic time (since roughly 1800) or exhibits evidence of surface displacement during Holocene time (Bryant and Hart, 2007; CGS, 2018). The definition of "potentially active" varies. A generally accepted definition of "potentially active" is a fault showing evidence of displacement that is older than 11,700 years (Holocene age) and younger than 2.6 million years (Pleistocene age). However, "potentially active" is no longer used as criteria for zoning by the California Geologic Survey (CGS). The terms "sufficiently active" and "well-defined" are now used by the CGS as criteria for zoning faults under the Alquist-Priolo (AP) Earthquake Fault Act. A "sufficiently active fault" is a fault that shows evidence of Holocene surface displacement along one or more of its segments and branches, while a "well-defined fault" is a fault whose trace is clearly detectable by a trained geologist as a physical feature at or just below the ground surface. The definition "inactive" generally implies that a fault has not been active since the beginning of the Pleistocene Epoch (older than 2.6 million years old).

The project site is east of and adjacent to the Casa Loma fault strand of the SJFZ, and the Casa Loma fault intersects the proposed onsite and confluence basins at the north end of the alignment and the proposed Line E inlet at the south end (USGS, 2006). The SJFZ has a geologic slip rate of 12-18 mm/year (Blisniuk et al. 2013; Rockwell et al. 2015). Paleoseismic data along the SJFZ indicate an average recurrence interval of surface-rupturing earthquakes of 185–254 years with moment magnitudes (Mw) ranging from 6.75 to 7.7 and per-event displacements of approximate 1.0 to 4.0 meters (Salisbury et al. 2012; Onderdonk et al. 2013; 2015; Rockwell et al. 2015).

5.4.2 Seismicity

The project is within the zone of influence for several faults which are considered active or potentially active and which are capable of producing seismic shaking at the site that could potentially be damaging to buildings and appurtenant structures. It is anticipated that the project site will periodically experience ground acceleration as the result of moderate to large magnitude earthquakes on faults outside the project area.

A number of earthquakes have occurred within the region of the site (approximately a 50-kilometer, or 31-mile, radius) during historic time (since 1800), including two earthquakes on

Copyright 2025 Kleinfelder

the SJFZ (Table 1). The largest of these historic earthquakes was a Mw 6.8 event on the SJFZ centered only 8 miles from the project area which resulted in ground rupture near the proposed Line E inlet at the south end of the project alignment.

Table 1
Historic Earthquakes within 50 km of Site (>Mw 4.9)

Earthquake Name	Distance (miles)	Magnitude (Mw)	Date	Latitude	Longitude
San Jacinto	8	6.8	4/21/1918	33.750014	-116.883430
North San Jacinto Fault	18	6.3	7/22/1923	33.999690	-117.238216
Elsinore	25	6	5/15/1910	33.749453	-117.450194
Big Bear	26	6.4	6/28/1992	34.175257	-116.867476
North Palm Springs	27	5.6	7/8/1986	33.998575	-116.608877

5.5 GROUNDWATER

Information on groundwater presented in this report is based on information derived from our geotechnical investigation, review of recent data from temporary groundwater observation wells installed in the vicinity of the project (SoCalGeo, 2022), and review of observation well water levels in the database of the State of California Department of Water Resources (DWR, 2021).

Groundwater was encountered in several borings drilled during this investigation in the floodplain of the San Jacinto River (Appendix A). Groundwater was measured in the borings when first encountered and then measured again at the completion of the borehole. Groundwater was encountered in 12 of the 19 borings drilled at depths ranging from approximately 6 feet to 33 feet bgs, with shallow water (6 to 12 feet bgs) encountered near the San Jacinto Reservoir adjacent to the south end of the alignment. There are several ponds or retention basins in the site vicinity, including the San Jacinto Reservoir, which may contribute to shallow water conditions, together with agriculture irrigation. Kleinfelder borings B-6, B-9, B-14, and B-15 were converted to piezometers and groundwater readings were taken following the field exploration, as summarized in the table below.

Copyright 2025 Kleinfelder

Table 2
Summary of Piezometer Groundwater Measurements

Date	Groundwater Depth (ft bgs)			
	B-6	B-9	B-14	B-15
Initial Drill Date	18.5 (9/27/2023)	17.5 (9/27/2023)	17.5 (9/26/2023)	18.5 (9/26/2023)
12/20/2023	7.5	14.8	15.8	16.0

We reviewed data from 16 temporary groundwater observation wells that were installed in the vicinity of the project as part of a proposed commercial/industrial development (SoCalGeo, 2022). The wells were installed at various depths, depending on the depth groundwater was encountered, and water level measurements were taken three times between January and March 2022. Groundwater levels in the wells were generally similar to the various depths groundwater was encountered during borehole drilling for the subject project, with the exception of four wells installed in and adjacent to the Casa Loma fault which did not encounter groundwater despite well depths of 61.5 to 66.5 feet bgs. The absence of groundwater along the Casa Loma fault may reflect the presence of recent, Holocene-age alluvium on the east side of the fault scarp but not on the west side (Morton et al., 2001).

There are several groundwater observation wells in the State database (DWR, 2021) showing data for 2021-2023 that are within or adjacent to the project footprint. Nearby wells on both sides of the Casa Loma fault were found to have similar groundwater depths of approximately 200 feet bgs. This observation suggests there is a lower aquifer with similar groundwater levels on both sides of the fault, and an upper (possibly perched) aquifer that is limited to the recent, Holocene-age alluvium that was deposited east of the Casa Loma fault scarp. The proposed project is located east of the fault where shallow groundwater is present.

5.6 GEOLOGIC HAZARDS

5.6.1 Fault Rupture

As discussed in Section 5.4.1, the Casa Loma strand of the SJFZ is adjacent to the north and south ends of the proposed drainage alignment, and the mapped trace of the fault (USGS, 2006) intersects the Line E inlet and basin facilities. The AP Fault Zone setback associated with the mapped fault traces (CGS, 2021) impinges on the proposed channel alignment at the south end near Bridge Street and Sanderson Avenue, and at the north end where the alignment crosses Record Road.

Copyright 2025 Kleinfelder

The AP Fault Zone setback does not appear conservative. Fault trench exploration and mapping performed about one-half mile northwest of the Line E inlet for a proposed residential development (Leighton, 2004) indicates that sections of the Casa Loma fault have numerous splays and that these fault splays effectively widen the fault zone by 250 feet or more.

Consequently, it is our opinion that the risk of surface fault rupture within the project alignment is high. A map presenting the location of the project alignment relative to the nearest faults is provided in Figure 3, Fault Location Map.

5.6.2 Flood Hazard

Based on Flood Hazard Maps available through the Federal Emergency Management Agency (FEMA) online service (FEMA, 2021), most of the project alignment lies within or adjacent to special flood hazard areas. Flood risk areas subject to inundation by a 1% annual chance flood (100-year flood) are presented (FEMA zone A or AE). Overall, the risk of flooding along the alignment is considered high. However, we anticipate construction of the proposed storm drain will warrant modifications to the referenced Flood Hazard Map. We anticipate the proposed storm drain improvements will decrease flood risk caused by potential flooding of the San Jacinto Reservoir south of the proposed alignment, however the proposed storm drain improvements would not change the flood risk caused by potential flooding of the San Jacinto River north of the proposed alignment.

5.6.3 Erosion

Erosion and sedimentation are natural processes that occur on slopes, hillsides, and natural drainages. The proposed storm drain alignment site is farmland on the distal margin of floodplain of the San Jacinto River and the risk of erosion is considered low to moderate, whereas the risk of sedimentation is considered moderate because the proposed open drainage channel will act as a sediment sink in the event of a flood. Scour and sedimentation analysis is beyond the scope of this study.

Copyright 2025 Kleinfelder

6 ENGINEERING CONCLUSIONS AND RECOMMENDATIONS

6.1 GENERAL

Based on the results of the field explorations, laboratory testing, and our engineering analyses conducted during this study, it is our professional opinion that the proposed project is geotechnically feasible provided the recommendations presented in this report are incorporated into the project design and construction. The following opinions, conclusions, and recommendations are based on the properties of the materials encountered in the field explorations, the results of the laboratory testing program, and our engineering analyses performed. Our recommendations regarding the geotechnical aspects of the design and construction of the project are presented in the following sections.

6.2 SEISMIC DESIGN CONSIDERATIONS

6.2.1 Seismic Design Parameters

According to ACSE/SEI 7-16 (2016), which is incorporated into the 2022 California Building Code (CBC) by reference, sites subject to liquefaction, as discussed below, should be classified as Site Class F, which requires a site response analysis. However, ACSE/SEI 7-16 states that for a short period (less than ½ second) structure on liquefiable soils, Site Class D or E may be used instead of Site Class F to estimate design seismic loading on the structure. The selection of Site Class D or E is based on the assessment of the site soil profile assuming no liquefaction. We have assumed that the period of the structures will be less than ½ second. The assumption that the structures have a period of less than ½ second should be verified by the project structural engineer.

Based on data obtained from our field explorations, published geologic literature and maps, and on our interpretation of the 2022 CBC criteria, it is our opinion that the project site may be classified as Site Class D, Stiff Soil, according to Section 1613 of 2022 CBC and Table 20.3-1 of ASCE/SEI 7-16 (2016). Approximate coordinates for the site are noted below.

- Latitude: 33.8208° N
- Longitude: 117.0247° W

In accordance with Section 11.4.8 of ASCE 7-16, a site-specific ground motion hazard analysis is required for Site Class D sites with an S1 greater than 0.2 g. However, a site-specific ground

Copyright 2025 Kleinfelder

motion hazard analysis is not required if the exceptions in Section 11.4.8 of ASCE 7-16 are taken. In accordance with the 2022 CBC, which adopts Supplement 3 of the ASCE 7-16, the exception would be if the values of the parameters S_{M1} and S_{D1} are increased by 50 percent. The assumption that the exception will be used should be verified by the project structural engineer during final design based on the governing code. Based on the assumption that the exception will be taken in accordance with the governing code, the 2022 CBC Seismic Design Parameters (non site-specific) for the project site are provided in Table 3.

Table 3
2022 CBC Seismic Design Parameters

DESIGN PARAMETER	RECOMMENDED VALUE
Site Class	D
S_s (g)	2.138
S_1 (g)	0.866
F_a	1.0
F_v	N/A*
S_{MS} (g)	2.138
S_{M1} (g)	N/A
S_{DS} (g)	1.425
S_{D1} (g)	N/A
PGA_M (g)	1.062

*Section 11.4.8 of ASCE 7-16 requires a site-specific ground motion hazard analysis be performed for Site Class D sites with S_1 values greater than or equal to 0.2g unless exceptions are taken. If exceptions are taken, then a F_v value of 1.7 could be used only to calculate the T_s value.

6.3 LIQUEFACTION AND SEISMICALLY INDUCED SETTLEMENT

Soil liquefaction is a phenomenon in which saturated, cohesionless soils lose their strength due to the build-up of excess pore water pressure during cyclic loading such as that induced by earthquakes. The primary factors affecting the liquefaction potential of a soil deposit are: 1) intensity and duration of earthquake shaking, 2) soil type and relative density, 3) overburden pressures, and 4) depth to groundwater. Soils most susceptible to liquefaction are clean, loose, uniformly graded, fine-grained sands, and non-plastic silts that are saturated. Silty sands and silts, under certain site conditions, may also be susceptible to liquefaction.

Generalized liquefaction potential zones have been mapped for areas of Riverside County (Riverside County, 2021). The zones are based on generalized criteria for sediment types,

Copyright 2025 Kleinfelder

groundwater levels, and ground shaking potential. Based on the screening criteria used to develop the generalized maps, the project alignment is identified as having a moderate potential for liquefaction.

The potential for liquefaction settlement in the vicinity of the proposed MWD pipeline crossing was evaluated using data from the CPTs performed for the project and CPT liquefaction assessment software (Cliq v.3.0.3.4). Although hollow stem auger borings were performed at the locations of potentially liquefiable soils, the blow count data is generally not as reliable as CPT data for liquefaction calculations. Samples collected from the borings and associated laboratory tests were used in verifying the CPT results.

The proposed MWD pipeline crossing area is underlain primarily by sandy silt and silty sand. The apparent density of the granular soil layers ranged from loose to medium dense. When encountered, groundwater levels in the borings ranged from approximately 6 to 33 feet below the ground surface. A design groundwater level of 5 feet bgs was used in the liquefaction calculations, which corresponds to the anticipated highest groundwater level at the site.

Two important input parameters for the liquefaction analysis are PGA and the earthquake magnitude. According to Chapter 18 of the 2022 California Building Code (CBC) the PGA used for liquefaction analysis should be consistent with the maximum considered earthquake ground motions. The 2022 CBC states that the peak ground acceleration shall be determined in accordance with Section 11.8.3 of ASCE 7-16. We determined the peak ground acceleration for each vault and transition structure location where liquefiable soils were present. The design PGA_M used in the liquefaction analysis was 1.06g. In order to estimate the controlling magnitude at the site, the 2014 USGS interactive deaggregation tool was used from the United States Geological Survey (USGS), and a dominant earthquake modal magnitude of 8.1 was calculated, utilizing a 2% exceedance probability in 50 years (return period of about 2,475 years) according to the 2022 CBC and ASCE/SEI 7-16.

Our analyses indicated that liquefaction could occur within interbedded sand layers throughout the upper 60 feet bgs. We have used procedures outlined in Moss et al. (2006) for CPT-based liquefaction triggering and estimation of volumetric compaction or settlement. Estimated total liquefaction-induced settlements in the vicinity of the proposed MWD pipeline crossing result in approximately 2 inches based on the CPT results. Based on the results of our field investigations, the subsurface soil conditions in the MWD pipeline crossing area is generally uniform. The CPTs were performed at locations approximately 300 feet from each other and the difference in liquefaction settlement results is less than ¼-inch. Based on these conditions,

Copyright 2025 Kleinfelder

differential liquefaction-induced settlement is considered generally negligible in the MWD pipeline crossing area. We have ignored any liquefaction and associated settlements below a depth of 60 feet, as their effects on the surface should be minimal. The results of our liquefaction calculations are included in Appendix C, Liquefaction Analysis.

It should be noted the calculated liquefaction settlement is a free-field settlement independent of existing or proposed improvements. Based on liquefaction analysis results by SoCalGeo (2021), other portions of the site in the vicinity of the proposed storm drain alignment may experience approximately 2 to 6 inches of liquefaction settlement during a design level earthquake event.

6.4 MWD PIPELINE CROSSING

6.4.1 Foundations

Based on the results of our field explorations, laboratory testing, and geotechnical analyses, the proposed MWD pipeline crossing may be supported on shallow footing foundations. Recommendations for the design and construction of shallow foundations are presented below.

Allowable Soil Bearing Pressure

Footings embedded at least 5 feet below the lowest adjacent exterior grade may be designed for a net allowable soil bearing pressure of 3,000 pounds per square foot (psf) for dead plus sustained live loads. The footing dimension and reinforcement should be designed by the structural engineer; however, continuous footings should have a minimum width of 18 inches. A one-third increase in the above bearing pressure can be used for transient wind or seismic loads.

Estimated Settlements

Based on design initial dead and service loads provided by the structural engineer, we estimate total static settlement of foundations designed and constructed in accordance with the recommendations presented above to be on the order of ½ inch for initial dead loads and grading and 1½ inches when including service and flood loads. Based on the generally granular nature of the subsurface soils, the initial dead load settlement is anticipated to be generally “immediate” (on the order of days to weeks). We understand the construction will be staged such that the initial dead load settlement will have occurred prior to allowing service loads to be imposed. Provided this construction staging is performed, total settlement of footings is

Copyright 2025 Kleinfelder

estimated to be up to 1 inch and differential static settlement between similarly loaded footings is estimated to be less than 1 inch over 50 feet.

In addition to the estimated static settlement, as previously discussed, it is estimated that liquefaction-induced settlement of saturated sandy soils due to strong ground shaking during an MCE-level seismic event could be on the order of 2 inches of total settlement, however, based on the generally uniform soil conditions in the MWD crossing area, differential liquefaction-induced settlement is considered generally negligible. We anticipate the liquefaction induced settlement impacts will be relatively similar between the crossing structure and the MWD pipe.

Lateral Resistance

Lateral load resistance may be derived from passive resistance along the vertical sides of the footings, friction acting at the base of the footing, or a combination of the two. An allowable passive resistance of 250 psf per foot of depth may be used for design. Allowable passive resistance values should not exceed 2,500 psf. An allowable coefficient of friction of 0.3 between the base of the footings and the on-site soils can be used for sliding resistance using the dead load normal stresses. Friction and passive resistance may be combined without reduction. We recommend that the first foot of soil cover be neglected in the passive resistance calculations if the ground surface is not protected from erosion or disturbance by a slab, pavement, or in a similar manner.

6.4.2 MWD Pipeline Settlement

Construction of the proposed storm drain would involve cuts and fills over the existing MWD pipeline. Grade changes, construction sequencing, flooding, and crossing structure footings could subject the MWD pipeline to change in loads that could cause settlement due to an increase in overburden stress or heave due to a decrease in overburden stress. We understand MWD requires proposed improvements in the vicinity of their pipe to not induce displacements on their pipe of more than ¼-inch per 100 feet. We have performed numerical modeling of the subsurface conditions and proposed structures using the 3-D finite element program PLAXIS 3D. The details and results of these analyses are included in Appendix E. The results of the analysis indicate the proposed improvements will meet MWD's tolerance provided the key recommendations and assumptions presented below are implemented in the design and construction of the crossing and storm drain.

Copyright 2025 Kleinfelder

The results of the analysis are presented in Appendix E, Numerical Analysis of Proposed Crossing. The key recommendations and assumptions utilized in the modeling that must be implemented in the design and construction of the crossing and storm drain channel are:

- Excavations will not be completed at a time when MWD has emptied the pipeline (i.e. it is not in-service).
- The crossing structure footings are constructed following the 1/3 sequence of excavation and footing placement.
    - Excavation of the subsequent 1/3 shall not progress until the footing for the previous 1/3 is in-place.
    - Excavation slopes and benches shall not be flatter than 1.5H:1V.
- Excavation and footing construction sequence shall be completed simultaneously on the upstream and downstream sides of the MWD pipeline. Simultaneously shall mean:
    - Elevations in excavations on either side shall not be more than 1 ft different.
    - The concrete footings shall be poured on both sides at the same time.
- Excavations shall not be backfilled until the full footing construction sequence is completed.
    - Backfill will consist of a medium weight flowable fill material (e.g. LCC) with a unit weight of approximately 85 pcf which does not require high vibration compactor equipment during placement. The medium weight flowable fill should have a friction angle of at least 30 degrees and cohesion of at least 50 psf.
    - Backfill shall be completed simultaneously on the upstream and downstream sides of the MWD pipeline. Simultaneously shall mean elevations of the backfill on each side shall not be more than 1 ft different.
- Lightweight flowable fill shall be used for embankments within 50 ft from the edge of the MWD pipe. Embankment fill shall consist of lightweight flowable fill material (e.g. LCC) not to exceed a unit weight of 30 pcf and does not require compaction to limit vibration impacts.
- Embankment fill shall be placed such that the elevation difference across (upstream to downstream sides) the MWD pipe is not greater than 1 ft at any time until final grades are established.

Copyright 2025 Kleinfelder

- The channel section shall limit the 100-yr flood event to a peak water elevation of 1453.47 ft.

6.4.3 Additional Constructability Considerations

Construction of the proposed MWD pipe crossing and storm drain in the vicinity of the existing MWD pipe while meeting MWD's requirements is considered feasible provided the key recommendations and assumptions utilized in the modeling provided above are implemented during design and construction. In addition, the following constructability considerations should also be considered based on MWD requirements.

- Vibrations on the MWD pipe should be less than 0.5 inches/second for "continuous" sources based on guidance provided by MWD. Based on Caltrans *Transportation and Construction Vibration Guidance Manual* (2020), vibratory rollers or similar equipment should not be used within 20 feet of the MWD pipe to meet MWD's limit.
- Any excavation within 2 feet of the MWD pipe should be performed by "hand" equipment as approved by MWD.
- Areas to receive fill that are not specified to require flowable fill as described above may utilize the on-site soil or import soil as structural fill in accordance with Section 6.9.
- Appropriate observations and inspections should be completed to ensure that the recommendations and assumptions made during our evaluation are followed during construction. Construction within the MWD right-of-way should conform to the relevant MWD construction standards, observations and inspections.

6.5 EXPANSIVE SOILS

Expansive soils are characterized by their ability to undergo significant volume change (shrink or swell) due to variations in moisture content. Changes in soil moisture content can result from rainfall, landscape irrigation, utility leakage, roof drainage, perched groundwater, drought, or other factors, and may cause unacceptable settlement or heave of structures, concrete slabs supported-on-grade, or pavements supported over these materials. Depending on the extent and location below finished subgrade, expansive soils can have a detrimental effect on structures.

In general, the soils encountered at the majority of the borings were silty or granular in nature. Laboratory testing resulted in Expansion Index values of 34 and 44, indicating a "low" expansion

Copyright 2025 Kleinfelder

potential. If import soil materials are used during construction, testing of the final subgrade soils should be performed to further evaluate the expansion potential.

6.6 CORROSIVITY

Selected near-surface soil samples from borings throughout the alignment were tested for potential corrosion to concrete and reinforcing steel. The samples were tested in general accordance with California Standard Test Methods to evaluate pH, minimum electrical resistivity, soluble sulfates, and chlorides content. These tests are only an indicator of soil corrosivity for the samples tested. Other soils found on site may be more, less, or of a similar corrosive nature.

Resistivity values ranged from 299 to 1,763 ohm-cm. Resistivity values less than 1,000 ohm-cm are considered extremely corrosive to buried ferrous metals. Resistivity values between 1,000 to 3,000 to ohm-cm are considered highly corrosive to buried ferrous metals (Roberge, 2006).

The concentrations of soluble sulfates indicate that the subsurface soils represent a Class S0 exposure to sulfate attack on concrete in contact with the soil based on ACI 318-19 Table 19.3.1.1 (ACI, 2019). Therefore, in accordance with ACI Building Code 318-19, no special provisions for selection of cement type are required.

The values obtained from corrosion potential testing are shown in Appendix B, Laboratory Testing. Kleinfelder's scope of services does not include corrosion engineering and, therefore, a detailed analysis of the corrosion test results is not included. We recommend the review of these results and consultation of a corrosion expert for further evaluation, if necessary.

6.7 TEMPORARY SHORING

6.7.1 General

Temporary shoring may be required where space or other restrictions do not allow a sloped excavation. Design and installation are the responsibility of the contractor. Temporary shoring may consist of a turn-key shoring system, soldier piles and lagging, or other system. Recommendations for design of temporary shoring are presented below.

The contractor's shoring design should be provided by a civil engineer registered in the State of California and experienced in the design and construction of shoring under similar conditions. Once the final excavation and shoring plans are complete, the plans and design should be

Copyright 2025 Kleinfelder

reviewed by Kleinfelder for conformance with the design intent and geotechnical recommendations provided herein.

6.7.2 Lateral Pressures

For the design of cantilevered shoring, an equivalent fluid pressure of 40 pounds per cubic foot (pcf) for drained conditions or 82 pcf for undrained conditions may be used for level backfill. Where the surface of the retained earth slopes up away from the shoring, a greater pressure should be used. Design data can be developed for additional cases when the design conditions are established.

In addition to the recommended earth pressure, any surcharge (live, including traffic, or dead load) located within a 1H:1V plane drawn upward from the base of the shored excavation should be added to the lateral earth pressures. The lateral contribution of a uniform surcharge load located immediately behind the wall may be calculated by multiplying the surcharge by 0.36 for the level backfill condition. Lateral load contributions of surcharges located at a distance behind the shored wall may be provided once the load configurations and layouts are known. As a minimum, a 2-foot equivalent soil surcharge (250 psf) is recommended to account for traffic or nominal construction loads. Stockpiled material should not be placed closer to the edge of an excavation than a distance equal to the depth of the excavation, and never closer than 4 feet from the edge of the excavation.

6.7.3 Design of Soldier Piles

All soldier piles should extend to a sufficient depth below the excavation bottom to provide the required lateral resistance. We recommend the required embedment depths be calculated based on the principles of force and moment equilibrium. For this method, the ultimate passive pressure against soldier piles that extend below the level of excavation may be assumed to be equivalent to a fluid pressure of 250 pcf, with a maximum resistance value of 2,500 psf. To account for arching, the passive resistance may be assumed to act over a width 2.0 times the width of the embedded portion of the pile, provided adjacent piles are spaced at least 3.0 pile diameters, center-to-center.

Drilling of the soldier pile shafts could be accomplished using heavy-duty drilling equipment. Groundwater may be encountered. The piles may be constructed partly below groundwater and, therefore, caving of the pile shafts should be anticipated and will need to be prevented. Temporary steel casing may be required to stabilize the sides of the pile shaft. Concrete for piles should be placed immediately after the drilling of the hole is complete. The concrete should

Copyright 2025 Kleinfelder

be pumped to the bottom of the drilled shaft using a tremie. Once concrete pumping is initiated, a minimum head of 5 feet of concrete above the bottom of the tremie should be established and maintained throughout the concrete placement to prevent contamination of the concrete by soil inclusions. If steel casing is used, the casing should be removed as the concrete is placed.

To develop full lateral resistance, provisions should be taken to assure firm contact between the soldier piles and undisturbed materials. The concrete placed in the soldier pile excavations may be a lean-mix concrete. However, the concrete used in that portion of the soldier pile that is below the planned excavated level should provide sufficient strength to adequately transfer the imposed loads to the surrounding materials.

6.7.4 Lagging

Continuous treated timber lagging and/or steel plates should be used between the soldier piles. The lagging/steel plates should be installed as the excavation proceeds. If treated timber is used, the lagging may remain in place after backfilling. The lagging should be designed for the recommended earth pressure but limited to a maximum value of 400 psf.

Some caving and running of the upper soils should be anticipated. To reduce the potential for loss of ground and settlement of the soil behind the wall, the contractor should backfill any space between the lagging and the cut slope with clean sand or sand-cement slurry after installation.

6.7.5 Deflection

Shoring adjacent to existing structures or improvements should be designed and constructed to reduce potential movement. The shoring system designer should evaluate potential deflections in their design. If the deflection analysis indicates excessive deflections, positive reinforcements such as tie backs may be needed.

6.7.6 Monitoring

Some deflection of the shored excavation should be anticipated during the planned excavation. We recommend the project civil engineer perform a survey of all existing utilities and structures adjacent to the shored excavation. The purpose of this survey would be to evaluate the ability of existing utility lines or improvements to withstand horizontal movements associated with a shored excavation and to establish the baseline condition in case of unfounded claims of

Copyright 2025 Kleinfelder

damage. If existing improvements are not capable of withstanding anticipated lateral movements, alternative shoring systems may be required.

Horizontal and vertical movements of the shoring system should be monitored by a licensed surveyor. The construction monitoring and performance of the shoring system are ultimately the contractor's responsibility. However, at a minimum, we recommend that the top of shoring be surveyed prior to excavation and that the top and bottom of the soldier beams be surveyed on a weekly basis until the shoring is not needed. Surveying should consist of measuring movements in vertical and two perpendicular horizontal directions.

6.8 REINFORCED CONCRETE BOX DESIGN

6.8.1 Design Parameters

The following geotechnical design recommendations are provided for the design of standard reinforced concrete box (RCB) for use along the entire storm drain project alignment.

Table 4
Standardized RCB Parameters

Soil Description	Sandy Silt to Silty Sand
Soil Density	110 pcf
Active Earth Pressure (Equivalent Fluid Pressure)	40 pcf (Drained) 20 pcf (Undrained***) 35 pcf (Seismic Increment*)
At-Rest Earth Pressure** (Equivalent Fluid Pressure)	60 pcf (Drained) 30 pcf (Undrained***)
Soil Cohesion	50 psf
Ultimate Passive Resistance	250 pcf
Coefficient of Friction	0.3
Allowable Net Bearing Pressure	2,000 psf

*Retaining structures supporting more than 6 feet of backfill should be designed to support an incremental seismic lateral pressure, which is applied as a triangular pressure distribution with a maximum pressure at the bottom of the retaining structure, similar to the active lateral earth pressure.

**For restrained retaining structures (at-rest condition), use the static active earth pressure and seismic increment to check the seismic condition; use at-rest earth pressure only to check the static condition; the larger loading of both cases should be used for the design of restrained retaining structure.

***Retaining structures should be designed with adequate drainage to reduce the potential for a buildup of hydrostatic pressures. For retaining structures where drainage outlets are not feasible, the undrained earth pressures listed above should be used. In addition to the above lateral pressures, walls should be designed to resist hydrostatic pressures. Hydrostatic pressures should assume a unit weight of 62.4 pcf and extend the full height of the wall. Hydrostatic pressure is applied as a triangular pressure distribution with a maximum pressure at the bottom of the wall, similar to the active lateral earth pressure. The resultant force may be assumed to at a height of 0.33H above the wall footing, where H is the retaining wall height.

Copyright 2025 Kleinfelder

6.8.2 Estimated RCB Settlement

The static settlement of individual RCB's will vary, depending on the depth of embedment, the plan dimensions of the vaults and the actual loading. We estimate the maximum total static settlement of vaults designed and constructed in accordance with the recommendations in this report to be on the order of 1 inch or less. Differential settlement is expected to be less than ½ inch, provided vaults are founded on similar materials. The estimated settlements discussed above do not include potential seismically-induced settlement discussed in Section 6.3.

6.9 EARTHWORK AND GRADING

Grading plans were not available for the project at the time this report was prepared. We anticipate earthwork and grading will be relatively minor. The final grading plans should be reviewed and, if needed, additional recommendations should be provided.

6.9.1 Site Preparation

All site preparation and earthwork operations should be performed in accordance with applicable codes, safety regulations, and other local, state, or federal specifications. All references to maximum unit weight should be established in accordance with the current ASTM Standard Test Method D1557 and may supersede references cited herein. The earthwork operations should be observed and tested by a representative of Kleinfelder.

6.9.2 Stripping and Grubbing

Prior to general site grading, existing pavement, vegetation, organic topsoil, existing fill soils, and debris shall be stripped and disposed of outside the construction limits. Deeper stripping or grubbing may be required where concentrations of fill debris, organic soils, existing trees, or thick root mats are encountered during site grading. Stripped topsoil (less any debris) may be stockpiled and reused for landscape purposes elsewhere on the project; however, this material should not be incorporated into any engineered fill.

In areas where existing trees will be removed, care should be taken to remove the root-ball, roots exceeding 1 inch in diameter, remaining organics, and to backfill the excavations with compacted engineered fill. We strongly recommend having a representative of Kleinfelder present during tree removal, in areas to receive fill or beneath foundations to observe removal of large roots and subsequent scarification and recompaction. Engineered fill should be placed and compacted in accordance with recommendations provided below.

Copyright 2025 Kleinfelder

6.9.3 Earthwork

At the RCB subgrade and storm drain bottoms, the exposed surface should be scarified to a minimum depth of 6 inches, moisture-conditioned, and compacted to at least 90 percent relative compaction. Any areas of loose or yielding soils should be over-excavated and re-compacted. Any soils that cannot be compacted, or are otherwise unsuitable for the planned use, should be excavated and disposed of from the project site and replaced with suitable engineered fill.

All materials to be placed as fill should be free of vegetation, organics, debris, and other deleterious materials. During fill placement, “oversize” material should be placed accordingly. Oversize material is any material with maximum dimension greater than 3 inches. All oversize material should be exported to an appropriate disposal facility. The larger rock, if any, will require special handling to reduce its size or place as windrows in a rock disposal fill.

All fill placed should be placed in horizontal lifts less than 8 inches in loose thickness, moisture-conditioned to within 2 percent of the optimum moisture content and compacted to 90 percent relative compaction per ASTM D1557. Engineered fill placed within the upper 12 inches of unpaved access roads or 12 inches below pavement subgrades should be compacted to at least 95 percent relative compaction of the maximum dry density obtained by ASTM D1557.

Import materials, if required, should have an Expansion Index (EI) of less than 20 with no more than 30 percent of the particles passing the No. 200 sieve and no particles greater than 3 inches in maximum dimension. The maximum EI for imported soils may be modified by the project geotechnical engineer depending on its proposed use. Imported fill should be documented to be free of hazardous materials, including petroleum or petroleum byproducts, chemicals and harmful minerals. Kleinfelder should evaluate the proposed imported materials prior to their transportation and use on site.

6.9.4 Temporary Excavations

All excavations must comply with applicable federal, state, and local safety regulations including the current OSHA Excavation and Trench Safety Standards. Construction site safety generally is the sole responsibility of the Contractor, who shall also be solely responsible for the means, methods, and sequencing of construction operations. We are providing the information below solely as a service to our client. Under no circumstances should the information provided be interpreted to mean that Kleinfelder is assuming responsibility for construction site safety or the Contractor’s activities. Such responsibility is not being implied and should not be inferred.

Copyright 2025 Kleinfelder

Temporary cut slopes up to 15 feet high may be sloped back at an inclination of no steeper than 1.5:1 (horizontal to vertical) in the existing site soils. Minor sloughing and/or raveling of sandy slopes should be anticipated as they dry out. If signs of slope instability are observed, the inclination recommended above should be decreased until stability of the slope is obtained. Kleinfelder should be onsite full time to observe the temporary backcuts. Where space for sloped embankments is not available, shoring will be necessary. All applicable excavation safety requirements and regulations, including OSHA requirements, should be met.

Where sloped excavations are used, the tops of the slopes should be barricaded so that vehicles and storage loads do not encroach the tops of excavated slopes within a distance equal to the depth of the excavation. Greater setback may be necessary when considering heavy vehicles, such as concrete trucks and cranes. Kleinfelder should be advised of such heavy vehicle loadings so that specific setback requirements can be established. If temporary construction slopes are to be maintained during the rainy season, berms are recommended along the tops of the slopes to reduce runoff that may enter the excavation and erode the slope faces. Stockpiled material should not be placed closer to the edge of an excavation than a distance equal to the depth of the excavation, and never closer than 4 feet from the edge of the excavation.

Temporary, shallow excavations with vertical side slopes less than 4 feet high should generally be stable, although sloughing may be encountered in the granular deposits. Vertical excavations greater than 4 feet high should not be attempted without appropriate shoring to prevent local instability. All trench excavations should be braced and shored in accordance with good construction practice and all applicable safety ordinances and codes. The contractor should be responsible for the structural design and safety of the temporary shoring system, and we recommend that this design be submitted to Kleinfelder for review to check that our recommendations have been incorporated. For planning purposes, the on-site soils may be considered as a Type C soil, as defined using the current OSHA soil classification.

6.9.5 Unstable Subgrade Conditions

Groundwater may be encountered during site grading. We recommend that a dewatering plan be prepared such that the groundwater is maintained below the storm drain subgrade elevation during construction. Following dewatering, we anticipate pumping subgrade conditions may be encountered, and the subgrade may need to be stabilized. An unstable subgrade could be over-excavated 12 to 24 inches below the subgrade elevation and replaced with an equal amount of ¾- or 1-inch compacted crushed rock wrapped by geotextile fabric. The geotextile fabric should

Copyright 2025 Kleinfelder

consist of a woven geotextile, such as Mirafi 600X or equivalent. The final depth of removal will depend upon the conditions observed in the field once over-excavation begins. The geotextile fabric should be placed in accordance with the manufacturer's recommendations. Alternate stabilization methods approved by Kleinfelder may also be performed.

6.10 PERMANENT SLOPES

Permanent slopes may be constructed for the proposed project. The following sections provide general recommendations for both fill and cut slopes. Revised recommendations may be needed based on our review of the final project plans.

6.10.1 Fill Slopes

Fill slopes may be inclined up to 2:1 (horizontal:vertical) or flatter. Where the toe of a fill slope terminates on a natural or cut slope, a keyway is required at the toe of the fill slope. The fill slope keyway should be a minimum width of 15 feet, with a minimum depth of 3 feet into competent natural material and should extend a distance equal to the depth of the keyway beyond the toe of the fill. Benching should be cut into the existing slope to bind the fill to the slope. Benches should be step-like in profile, with each bench not less than four feet in height and established in competent material. Figure 4, Typical Engineered Fill Slope Detail shows a typical section for a fill slope including keyway and benching. For slopes 10 feet high or less, the keyway depth and width may be reduced as presented in Table 5 below.

Table 5
Minimum Keyway Recommendations

Keyway Recommendations for Fill Slopes			
Slope Height	5 feet or less	> 5 feet to 10 feet	> 10 feet
Minimum Keyway Depth	1 foot into competent material	2 feet into competent material	3 feet into competent material
Minimum Keyway Width	8 feet *	8 feet	15 feet

* For fill slopes 5 feet or less in height, further evaluation of the keyway width can be made by the Engineer of Record based on field conditions and construction methods employed.

Compressible or other unsuitable soils should be removed from the slope prior to benching. Competent material is defined as being essentially free of loose soil, heavy fracturing or erosion prone material and is established by the Geotechnical Consultant during grading. Following

Copyright 2025 Kleinfelder

completion of the excavation for the keyway, the project Geotechnical Consultant shall observe the keyway prior to backfilling with certified engineered fill.

Depending on fill slope construction and actual site conditions encountered in the field to be verified by the Geotechnical Engineer or their representative, back drains may be required within the compacted fill to prevent the buildup of hydrostatic pressures behind the fill slope. Field conditions, such as observed seepage, or the presence of water within the slope may require the use of subdrains to adequately prevent buildup of hydrostatic pressures behind the fill slope. In general, fill slopes with design heights less than 10 feet will likely not require subdrains.

When constructing fill slopes, the contractor shall avoid spillage of loose material down the face of the slope during dumping and rolling conditions. Preferably, the incoming load shall be dumped behind the face of the slope and bladed into place. As a preferred method, the slope should be over-built and then trimmed back to expose a compacted core. As an alternative method, after each 4 feet of vertical height has been obtained, the contractor shall compact the outer face of the slope by backing the tamping roller over the top of the slope and thoroughly covering the entire slope surface with overlapping passes of the roller and accepted by geotechnical engineer of record. The foregoing should be repeated after the placement of each 4-foot thickness of fill.

As discussed previously, fill slopes should conform to the requirements of the “Earthwork” section of this report and should contain no particles greater than 3 inches in maximum dimension. The fill slope surface should be compacted to a minimum of 90 percent relative compaction per ASTM D1557, or as specified in the project plans and specifications. Surface drainage control, such as berms at the tops of slopes, should be included in the design of fill slopes to direct sheet flow away from the tops of slopes and reduce the potential for slope erosion.

6.10.2 Cut Slopes

In general, cut slopes should be a maximum inclination of 2:1 (horizontal:vertical). Due to the potential for adverse geologic conditions, cut slopes proposed in formational material should be evaluated on a case-by-case basis. We recommend that a qualified geologist be on site during grading of the cut slopes to map the exposed geology for consistency with the conditions presented in this report. Revised recommendations may be needed based on the in-grading mapping.

Copyright 2025 Kleinfelder

6.11 EXCAVATION CHARACTERISTICS

In general, the drilling equipment used for our geotechnical investigation was able to reach the target depths at all of the borings, suggesting that the subsurface soils can be excavated with conventional excavation equipment.

6.12 SCOUR CONSIDERATIONS

We understand scour analysis will be performed by others. The near-surface soil generally consisted of sandy silt and silty sand. The sieve analysis results presented in Appendix B can be used to support scour analyses. The grain size representing percent passing 50% (D_{50}) obtained from the sieve analyses of the near-surface soil are summarized in Table 6 below.

Table 6
D_{50} Results

Boring Number	Depth (ft)	D_{50} (mm)
B-1	5	0.072
B-2	5	0.045
B-3	0 – 5	>0.1
B-4	0 – 5	0.14
B-5	5	0.025
B-6	0 – 5	0.040
B-7	0 – 5	0.094
B-8	5	0.052
B-9	5	0.13
B-10	0 – 5	0.067
B-11	0 – 5	0.071

6.13 PAVEMENT RECOMMENDATIONS

6.13.1 Asphalt Concrete

If proposed access roads will be paved, the required pavement structural sections will depend on the expected wheel loads, volume of traffic, and subgrade soils. The Traffic Indexes (TI's) assumed should be reviewed by the project Owner, Architect, and/or Civil Engineer to evaluate their suitability for this project. Changes in the TI's will affect the corresponding pavement section. The pavement subgrade should be prepared just prior to placement of the base course. Positive drainage of the paved areas should be provided since moisture infiltration into the subgrade may decrease the life of pavements. A preliminary asphalt concrete pavement section is provided in Table 7, below.

Table 7
Preliminary Asphalt Concrete Pavement Sections
(Design R-value = 50)

Assumed Traffic Index (TI)	Minimum Asphalt Concrete (inches)	Minimum Aggregate Base (inches)
5	3.0	4.0

Based on laboratory testing results, a design R-Value of 50 was selected for pavement design. Since the characteristics of the near-surface soils can change as a result of grading, we recommend that representative subgrade samples be obtained during grading and additional R value tests performed. Should the results of these tests indicate a significant difference, the design pavement section(s) provided above may need to be revised. Pavement sections provided above are contingent on the following recommendations being implemented during construction.

- The upper 12 inches of subgrade below pavements should be compacted to at least 95 percent relative compaction.
- Subgrade soils should be in a stable, non-pumping condition at the time aggregate base materials are placed and compacted.
- Aggregate base materials should be compacted to at least 95 percent relative compaction.
- Adequate drainage (both surface and subsurface) should be provided such that the subgrade soils and aggregate base materials are not allowed to become wet.

Copyright 2025 Kleinfelder

- Aggregate base materials should meet current Caltrans specifications for Class II aggregate base rock or crushed miscellaneous base as specified in the "Standard Specifications for Public Work Construction" ("Greenbook").
- The asphalt pavement should be placed in accordance with “Green Book” specifications or the City of San Jacinto requirements, as appropriate. We recommend that the asphalt pavement be placed in a single layer of ½-inch aggregate mix for pavements 4 inches thick or less. If the pavement section is over 4 inches thick, then the asphalt should be placed in at least two layers of mix. The first layer should consist of a base or coarse layer (¾-inch mix). The second layer (i.e., top layer) should consist of a medium or fine layer of ½-inch mix.

6.13.2 Portland Cement Concrete

Portland cement concrete (PCC) pavement should have a minimum 28-day compressive strength of 3,000 psi. Control joints should be spaced approximately every 10 feet. The concrete pavement section should be placed on at least 18 inches of engineered fill compacted to at least 90 percent of the maximum dry density with the upper 12 inches below pavements compacted to at least 95 percent relative compaction. Prior to fill placement, the exposed subgrade should be scarified to a depth of 8 inches, uniformly moisture conditioned to near optimum moisture content at the time of compaction. The following table presents our recommendations of Portland Cement Concrete pavement sections.

Table 8
Preliminary PCC Pavement Sections

Assumed Traffic Index (TI)	Minimum Concrete Thickness (inches; using a 28-day compressive strength of 3,000 psi)	Minimum Concrete Thickness (inches; using a 28-day compressive strength of 4,000 psi)
5	6.5	6.0

As an alternative to placing PCC pavements directly over 18 inches of engineered fill, 6 inches of aggregate base material may be added between the PCC and engineered fill to provide additional load distribution, drainage, and an option to reduce the thickness of the recommended PCC. If 6 inches of aggregate base material (compacted to 95% relative compaction) is used between the recommended 18 inches of engineered fill and PCC pavement, the recommended PCC thickness may be reduced by ½ inch. Aggregate base materials should meet current Caltrans specifications for Class 2 aggregate base or crushed

miscellaneous base as specified in the "Standard Specifications for Public Work Construction" ("Greenbook").

7 LIMITATIONS

Recommendations contained in this report are based on our field observations and subsurface explorations, laboratory tests, and our present knowledge of the proposed project. It is possible that soil conditions could vary between or beyond the points explored. If soil conditions are encountered during construction, which differ from those described herein, we should be notified immediately in order that a review may be made and any supplemental recommendations provided. If the scope of the proposed project, including the proposed foundation systems or vault locations, change from that described in this report, our recommendations should also be reviewed and a response issued. References to elevations and locations provided within this report were based upon general information provided for our use. Kleinfelder did not provide surveying services.

Other standards or documents referenced in any given standard cited in this report, or otherwise relied upon by the authors of this report, are only mentioned in the given standard; they are not incorporated into it or "included by reference," as the latter term is used relative to contracts or other matters of law.

We have strived to prepare the findings, conclusions, and recommendations in this report in a manner consistent with the standards of care and skill ordinarily exercised by members of this profession practicing under similar conditions in the geographic vicinity and at the time the services were performed. No warranty or guarantee, express or implied, is made. Information and recommendations presented in this report should not be extrapolated to other areas or be used for other projects without our prior review and response.

This report may be used only by Albert A. Webb Associates and their subcontractors and only for the purposes stated, within a reasonable time from its issuance. Land use, site conditions (both on site and off site) or other factors may change over time, and additional work may be required with the passage of time. Any party other than Albert A. Webb Associates and their subcontractors who wishes to use this report shall notify Kleinfelder of such intended use. Based on the intended use of the report, Kleinfelder may require that additional work be performed and that an updated report be issued. Non-compliance with any of these requirements by the client or anyone else will release Kleinfelder from any liability resulting from the use of this report by any unauthorized party.

Copyright 2025 Kleinfelder

Kleinfelder will assume no responsibility or liability whatsoever for any claim, damage, or injury which results from pre-existing hazardous materials being encountered or present on the project site, or from the discovery of such hazardous materials.

DETAIL A:

PERFORATED PIPE SURROUNDED BY FILTER MATERIAL

FILTER MATERIAL:
Filter material shall be class 2 permeable material per State of California Standards Specifications, or an approved alternate.

NOTES:

1) FINAL BENCHING AND KEYWAY EXCAVATION DEPTHS AND DETAILS SUBJECT TO EVALUATION OF FIELD CONDITIONS.
2) DIMENSIONS AND LOCATIONS OF SUB DRAINAGE ARE APPROXIMATE. ACTUAL INSTALLATION TO BE BASED ON FIELD CONDITIONS.
3) GRADE PIPES TO DRAIN TO AN APPROPRIATE DISCHARGE FACILITY.
4) INSTALL CLEANOUTS AT ENDS, ANGLES, AND JUNCTIONS OF PIPE.
5) BENCH SHALL BE REQUIRED WHEN NATURAL SLOPES ARE EQUAL TO OR STEEPER THAN 5:1 OR WHEN RECOMMENDED BY THE FIELD ENGINEER.
6) SUBDRAINAGE: BACK DRAIN SHOULD BE REQUIRED AT THE DISCRETION OF THE GEOTECHNICAL CONSULTANT.

APPENDIX A
FIELD EXPLORATION

Copyright 2025 Kleinfelder

APPENDIX A
FIELD EXPLORATION

Field explorations included a site reconnaissance and subsurface explorations. During the site reconnaissance phase, each proposed boring site was visited to evaluate exploration equipment, accessibility, and general site conditions. The subsurface exploration program included drilling 19 hollow-stem auger borings and performing 2 CPTs.

The borings were drilled to depths ranging from approximately 20 to 50 feet bgs. Truck-mounted hollow-stem auger drill rigs supplied by 2R Drilling of Chino, California were used for the soil borings. Hollow-Stem Auger (HSA) drill rigs were equipped with 8-inch outside diameter (O.D.) continuous flight, hollow-stem augers.

The CPTs were advanced to a maximum depth of 100 ft bgs. The CPTs were performed by Kehoe Testing & Engineering, Inc. of Huntington Beach, California using a 30-ton truck rig.

Disturbed and relatively undisturbed samples of the subsurface materials were obtained from the borings using Standard Penetration test (SPT) samplers and California-type (CAL) samplers, respectively. The SPT sampler has a 1.375-inch inside diameter and a 2.0-inch outside diameter. The CAL sampler has a 2.42-inch inside diameter and a 3.0-inch outside diameter. Samples were driven 18 inches into the soil using a 140-pound automatic hammer falling 30 inches. SPT and CAL samples were obtained at 5-foot intervals alternating between the SPT and the CAL until reaching the boring target depth. Large bulk samples were also obtained within the upper 5 feet from each boring. The number of blows required to drive the samplers were recorded for each 6-inch penetration interval. The number of blows required to drive the samplers for the last 12 inches, or the interval achieved where higher resistance was encountered, is referred to as the blow count and is noted on the boring logs. Where the sample was driven less than 12 inches, the number of blows to drive the sample for each 6-inch segment, or portion thereof, is shown on the logs. For example, 50/4" indicates 50 blows to drive the sampler 4 inches to refusal. After the samplers were withdrawn from the test borings, select samples were carefully removed, sealed to reduce moisture loss, and transported to AP Engineering and Testing, Inc. for testing.

A legend to the logs is presented as Figure A-1 and A-2. The boring logs are presented as Figure A-3 through A-24. The logs describe the earth materials encountered, indicate the locations of the samples obtained, and show field and laboratory tests performed. The excavations were logged by an engineer from Kleinfelder using methods outlined in the Unified Soil Classification System (USCS) and general procedures established in ASTM D2488. The

Copyright 2025 Kleinfelder

boundaries between soil types shown on the logs are approximate because the transition between different soil layers may be gradual. The CPT visual plots and data are also attached in Appendix A following the logs.

NOTES

- The report and graphics key are an integral part of these logs. All data and interpretations in this log are subject to the explanations and limitations stated in the report.
- Solid lines separating strata on the logs represent approximate boundaries only, dashed lines are inferred or extrapolated boundaries. Actual transitions may be gradual or differ from those represented.
- No warranty is provided as to the continuity of soil or rock conditions between individual sample locations.
- Logs represent general soil or rock conditions observed at the point of exploration on the date indicated.
- In general, Unified Soil Classification System (ASTM D2488/D2487) designations presented on the logs were based on visual classification in the field and were modified where appropriate based on gradation and index property testing.
- Fine grained soils that plot within the hatched area on the Plasticity Chart, and coarse grained soils with between 5% and 12% passing the No. 200 sieve require dual USCS symbols, ie., CL-ML, GW-GM, GP-GM, GW-GC, GP-GC, GC-GM, SW-SM, SP-SM, SW-SC, SP-SC, SC-SM.
- If sampler is not able to be driven at least 6 inches then 50/X indicates number of blows required to drive the identified sampler X inches with a pound hammer falling inches.

Fines		Passing #200	<0.0029 in. (<0.07 mm.)

SECONDARY CONSTITUENT[1]

Term of Use	AMOUNT	
	Secondary Constituent is Fine Grained	Secondary Constituent is Coarse Grained
Trace	<5%	<15%
With	≥5 to <15%	≥15 to <30%
Modifier	≥15%	≥30%

PLASTICITY[1]

DESCRIPTION	CRITERIA
Non-Plastic	A 1/8 in. (3 mm) thread cannot be rolled at any water content.
Low	The thread can barely be rolled and the lump cannot be formed when drier than the plastic limit.
Medium	The thread is easy to roll and not much time is required to reach the plastic limit. The thread cannot be rerolled after reaching the plastic limit. The lump crumbles when drier than the plastic limit.
High	It takes considerable time rolling and kneading to reach the plastic limit. The thread can be rerolled several times after reaching the plastic limit. The lump can be formed without crumbling when drier than the plastic limit.

MOISTURE CONTENT[1]

DESCRIPTION	FIELD TEST
Dry	Absence of moisture, dusty, dry to the touch
Moist	Damp but no visible water
Wet	Visible free water, usually soil is below water table

CONSISTENCY - FINE-GRAINED SOIL[2, 3]

CONSISTENCY	SPT - N (# blows / ft)	Pocket Pen (tsf)	UNCONFINED COMPRESSIVE STRENGTH (Q_u)(psf)	VISUAL / MANUAL CRITERIA
Very Soft	<2	PP < 0.25	<500	Easily penetrated several inches by fist
Soft	2 - 4	0.25 ≤ PP <0.5	500 - 1,000	Easily penetrated several inches by thumb
Medium Stiff	4 - 8	0.5 ≤ PP <1	1,000 - 2,000	Can be penetrated several inches by thumb with moderate effort
Stiff	8 - 15	1 ≤ PP <2	2,000 - 4,000	Readily indented by thumb but penetrated only with great effort
Very Stiff	15 - 30	2 ≤ PP <4	4,000 - 8,000	Readily indented by thumbnail
Hard	>30	4 ≤ PP	>8,000	Indented by thumbnail with difficulty

APPARENT DENSITY - COARSE-GRAINED SOIL[2]

APPARENT DENSITY	SPT-N (# blows / ft)
Very Loose	<4
Loose	4 - 10
Medium Dense	10 - 30
Dense	30 - 50
Very Dense	>50

STRUCTURE[1]

DESCRIPTION	CRITERIA
Stratified	Alternating layers of varying material or color with layers at least 1/4-in. (6mm) thick, note thickness.
Laminated	Alternating layers of varying material or color with the layers less than 1/4-in. (6 mm) thick, note thickness.
Fissured	Breaks along definite planes of fracture with little resistance to fracturing.
Slickensided	Fracture planes appear polished or glossy, sometimes striated.
Blocky	Cohesive soil that can be broken down into small angular lumps which resist further breakdown.
Lensed	Inclusion of small pockets of different soils, such as small lenses of sand scattered through a mass of clay; note thickness.
Homogeneous	Same color and appearance throughout

ANGULARITY[1]

DESCRIPTION	CRITERIA
Angular	Particles have sharp edges and relatively plane sides with unpolished surfaces.
Subangular	Particles are similar to angular description but have rounded edges.
Subrounded	Particles have nearly plane sides but have well-rounded corners and edges.
Rounded	Particles have smoothly curved sides and no edges.

REACTION WITH HYDROCHLORIC ACID[1]

DESCRIPTION	FIELD TEST
None	No visible reaction
Weak	Some reaction, with bubbles forming slowly
Strong	Violent reaction, with bubbles forming immediately

CEMENTATION[1]

DESCRIPTION	FIELD TEST
Weakly	Crumbles or breaks with handling or little finger pressure
Moderately	Crumbles or breaks with considerable finger pressure
Strongly	Will not crumble or break with finger pressure

The boring was terminated at approximately 21.5 ft. below ground surface. The boring was backfilled with auger cuttings on September 26, 2023.

GROUNDWATER LEVEL INFORMATION:
▽ Groundwater was observed at approximately 21 ft. below ground surface during drilling.
▼ Groundwater was observed at approximately 17.5 ft. below ground surface at the end of drilling.

GENERAL NOTES:
The exploration location and elevation are approximate and were estimated by Google Earth.

The boring was terminated at approximately 21.5 ft. below ground surface. The boring was backfilled with auger cuttings on September 26, 2023.

GROUNDWATER LEVEL INFORMATION:
▽ Groundwater was observed at approximately 10.5 ft. below ground surface during drilling.
▼ Groundwater was observed at approximately 8 ft. below ground surface after drilling completion.

GENERAL NOTES:
The exploration location and elevation are approximate and were estimated by Google Earth.

APPENDIX B
LABORATORY TESTING

Copyright 2025 Kleinfelder

APPENDIX B
LABORATORY TESTING

Laboratory tests were performed on drive and bulk soil samples to estimate engineering characteristics of the various earth materials encountered. Testing was performed by Kleinfelder's Ontario, California lab and AP Engineering & Testing, Inc. (AP) of Pomona, California. The test results are presented herein. Visual classifications presented on the lab plates were performed by AP during their laboratory testing and may differ from those presented on the boring logs provided in Appendix A.

IN-SITU MOISTURE CONTENT AND DRY UNIT WEIGHT

In-situ moisture content and dry unit weight tests were performed on samples that could be recovered in a relatively undisturbed condition. Moisture content was evaluated in general accordance with ASTM Test Method D2216. Dry unit weight was evaluated in general accordance with ASTM Test Method D7263. The results are presented on the boring logs in Appendix A.

WASH SIEVE

To provide information on the fines content of the soil layers at the site, wash sieves were performed to determine the percentage passing the #200 sieve. The wash sieves were performed in accordance with ASTM Test Method D1140. The results are presented on the boring logs in Appendix A.

GRAIN SIZE DISTRIBUTION

Sieve & hydrometer analyses were performed on soil samples to evaluate the gradation of the material and to aid in soil classification. Tests were performed in general accordance with ASTM Standard Test Method D6913. The results are presented on the boring logs in Appendix A and in the attached laboratory data in Appendix B.

ATTERBERG LIMITS (PLASTICITY INDEX)

Plasticity limit and liquid limit testing was performed on soil samples to evaluate behavior conditions at varying water contents. Testing was performed in general accordance with ASTM Standard Test Method D4318. The results are presented on the boring logs in Appendix A and in the attached laboratory data in Appendix B.

Copyright 2025 Kleinfelder

DIRECT SHEAR

Direct shear strength tests were performed by AP on drive samples to evaluate the drained shear strength of the onsite soils. Samples were tested in a near-saturated condition in general accordance with ASTM Test Method D 3080 (consolidated, drained). The results are presented in the attached laboratory data in Appendix B.

CONSOLIDATION TEST

Consolidation testing was performed by AP on selected relatively undisturbed samples by AP Engineering in accordance with ASTM D 2435. The tests were performed on 1.0-inch-high, 2.41-inch diameter samples. After trimming the ends, the sample was placed in a consolidometer and an initial reading was recorded. The sample was saturated during loading, and thereafter, the sample was incrementally loaded. The results are presented in the attached laboratory data in Appendix B.

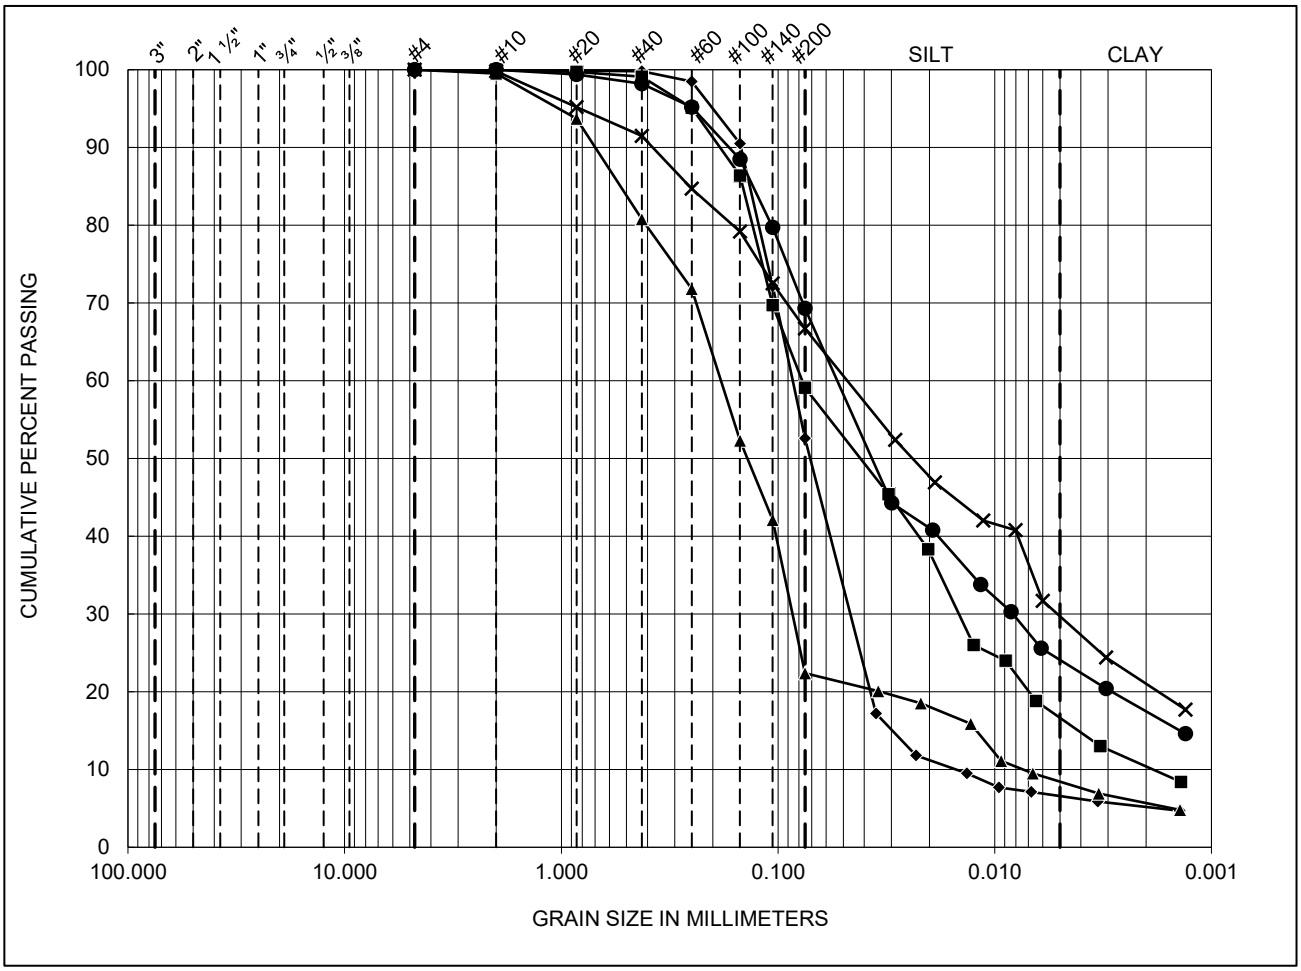
EXPANSION INDEX

Expansion Index testing was performed on near surface bulk samples to determine the expansion potential of the soil. The testing was performed in accordance with ASTM Standard Test Method D4829. The results are presented in the attached laboratory data in Appendix B.

COMPACTION TESTING (MAXIMUM DRY DENSITY-OPTIMUM MOISTURE)

Maximum dry density-optimum moisture tests were performed on select bulk samples of the on-site soils to determine compaction characteristics. The tests were performed in accordance with ASTM Standard Test Method D1557. The results are presented in the attached laboratory data in Appendix B.

R-VALUE TESTING



Resistance value (R-value) tests were performed on bulk soil samples obtained to evaluate pavement support characteristics of the near-surface onsite soils. R-value tests were performed in accordance with ASTM Standard Test Method D2844. The results are presented in the attached laboratory data in Appendix B.

Copyright 2025 Kleinfelder

CORROSIVITY TESTS

Chemical analyses were performed on samples of the near surface soil by AP to estimate pH, minimum resistivity, soluble sulfate, and chloride contents. The tests were performed in accordance with Caltrans standards. The results are presented in the attached laboratory data in Appendix B.

1 INTRODUCTION

In-situ seismic measurements using active- and passive-source surface wave techniques were performed along two transects in San Jacinto, California. The purpose of this investigation was to provide a shear (S) wave velocity profile to a depth of 100 feet at 5 (or more) test locations per transect. The active-source surface wave technique utilized during this investigation consisted of the multi-channel analysis of surface waves (MASW) method. The passive-source surface wave technique consisted of the linear array microtremor method. The locations of the active- and passive-source surface wave arrays are shown on Figure 1 and Table 1.

At many sites, active surface wave techniques (MASW) with the utilization of portable energy sources, such as hammers and weight drops, are sufficient to obtain S-wave velocity soundings to 100 ft depths. At sites with high ambient noise levels and/or very soft soils, these energy sources may not be sufficient to image to this depth and a larger energy source, such as a bulldozer, is necessary. Alternatively, passive surface wave techniques, such as the array microtremor technique can be used to extend the depth of investigation at sites that have adequate ambient noise conditions.

This report contains the results of the active and passive surface wave measurements conducted at the site. An overview of the surface wave methods is given in Section 2. Field and data reduction procedures are discussed in Sections 3 and 4, respectively. Data modeling is presented in Section 5 and results are discussed in Section 6. References and our professional certification are provided in Sections 7 and 8, respectively.

2 Overview of Surface Wave Techniques

2.1 Introduction

Active- and passive-source (ambient vibration) surface wave techniques are routinely utilized for site characterization. Active surface wave techniques include the spectral analysis of surface waves (SASW) and multi-channel array surface wave (MASW) methods. Passive surface wave techniques include the horizontal over vertical spectral ratio (HVSR) technique and the array and refraction microtremor methods.

The basis of surface wave methods is the dispersive characteristic of Rayleigh and Love waves when propagating in a layered medium. Surface waves of different wavelengths (λ) or frequencies (f) sample different depth. As a result of the variance in the shear stiffness of the distinct layers, waves with different wavelengths propagate at different phase velocities; hence, dispersion. A surface wave dispersion curve is the variation of V_R or V_L with λ or f. The Rayleigh wave phase velocity (V_R) depends primarily on the material properties (V_S, mass density, and Poisson's ratio or compression wave velocity) over a depth of approximately one wavelength. The Love wave phase velocity (V_L) depends primarily on V_S and mass density. Rayleigh and Love wave propagation are also affected by damping or seismic quality factor (Q). Rayleigh wave techniques are utilized to measure vertically polarized S-waves (S_V-wave); whereas Love wave techniques are utilized to measure horizontally polarized S-waves (S_H-wave).

2.2 Surface Wave Techniques

The MASW and array microtremor techniques were utilized during this investigation and are discussed below.

2.2.1 MASW Technique

A description of the MASW method is given by Park, 1999a and 1999b and Foti, 2000. Ground motions are typically recorded by 24 or more geophones spaced 1 to 3 m apart along a linear array and connected to a seismograph. Energy sources for shallow investigations include various sized hammers and vehicle mounted weight drops. When applying the MASW technique to develop a one-dimensional (1-D) V_S model, it is preferable to use multiple-source offsets from both ends of the array. The most commonly applied MASW technique is the Rayleigh-wave based MASW method, which we refer to as MAS_RW to distinguish from Love-wave based MASW (MAS_LW). MAS_RW and MAS_LW acquisition can easily be combined with P- and S-wave seismic refraction acquisition, respectively. MAS_RW data are generally recorded using a vertical source and vertical geophone but may also be recorded using a horizontal geophone with radial (in-line) orientation. MAS_LW data are recorded using transversely orientated horizontal source and transverse horizontal geophone.

A wavefield transform is applied to the time-history data to convert the seismic record from time-offset space to frequency-wavenumber (f-k) space in which the fundamental or higher surface-wave modes can be easily identified as energy maxima and picked. Frequency and/or wavenumber can easily be mapped to phase velocity, slowness, or wavelength using the following properties: $k = 2\pi/\lambda$, $\lambda = v/f$. Common wave-field transforms include: the f-k transform, slant-stack transform, frequency domain beamformer, and phase-shift transform. The

minimum wavelength that can be recovered from MASW data set without spatial aliasing is equal to the minimum receiver spacing. Occasionally, SASW analysis procedures are used to extract surface wave dispersion data, from fixed receiver pairs, at smaller wavelengths than can be recovered by wavefield transformation. Multiple source offsets, and limiting minimum and maximum wavelengths, are required to construct a dispersion curve bandwidth necessary to develop a robust V_S model (Yoon and Rix, 2009; Li and Rosenblad, 2011).

Although the clear majority of MASW surveys record Rayleigh waves, it has been shown that Love wave techniques can be more effective in some environments, particularly shallow rock sites and sites with a highly attenuative, low velocity surface layer (Xia, et al., 2012; **GEO***Vision*, 2012). Rayleigh wave techniques, however, are generally more effective at sites where velocity gradually increases with depth because larger energy sources are readily available for the generation of Rayleigh waves. Rayleigh wave techniques are also more applicable to sites with high velocity layers and/or velocity inversions because the presence of such structures is more apparent in the Rayleigh wave dispersion curves than in Love wave dispersion curves. Rayleigh wave techniques are preferable at sites with a high velocity surface layer because Love waves do not theoretically exist in such environments. Joint inversion of Rayleigh and Love wave data may yield more accurate V_S models in anisotropic materials.

2.2.2 Array Microtremor Technique

A detailed discussion of the array microtremor method can be found in Okada, 2003. Unlike active source techniques, the array microtremor technique (also referred to as passive surface wave method) records ambient noise and ground motions emanating from ocean wave activity, wind noise, traffic, industrial activity, construction, etc. The technique uses 4 or more receivers aligned in a 2-dimensional array. Triangle, circle, semi-circle, and “L” shaped arrays are commonly used, although any 2-dimensional arrangement of receivers can be used. For investigations of the upper 100 m, receivers typically consist of 1 to 4.5 Hz geophones. For deeper investigations, 5 to 120 s seismometers are generally utilized.

The surface wave dispersion curve is typically estimated from array microtremor data using various f-k methods such as beamforming (Lacoss, et al., 1969), and maximum-likelihood (Capon, 1969), and the spatial-autocorrelation (SPAC) method. The SPAC method was originally based on work by Aki (1957) and has since been extended and modified (Ling and Okada, 1993 and Ohori *et al*., 2002) to permit the use of noncircular arrays, and is now collectively referred to as extended spatial autocorrelation (ESPAC or ESAC). SPAC methods are expected to perform better when noise sources are azimuthally well-distributed (e.g., in a large urban area). The minimum wavelength surface wave that can be extracted from an array microtremor dataset acquired utilizing a symmetric array is typically set equal to the minimum receiver spacing. The maximum wavelength is often set equal to twice the maximum receiver separation for SPAC analysis.

2.3 Surface Wave Dispersion Curve Modeling

The dispersion curves generated from the active and passive surface wave soundings are generally combined and modeled using iterative forward and inverse modeling routines. The final model profile is assumed to represent actual site conditions. The theoretical model used to interpret the dispersion curve assumes horizontally layered, laterally invariant, homogeneous-isotropic material. Although these conditions are seldom strictly met at a site, the results of active and/or passive surface wave testing provide a good "global" estimate of the material properties along the array. The results may be more representative of the site than a borehole "point" estimate.

MAS_RW and/or passive surface-wave modeling may involve modeling of the fundamental mode, some form of effective mode, or multiple individual modes (multi-mode). The fundamental mode assumption is generally applicable to modeling Rayleigh-wave dispersion data collected at normally dispersive sites, providing there are not abrupt increases in velocity or steep velocity gradients. Effective-mode or multi-mode approaches are often required for irregularly dispersive sites and sites with steep velocity gradients at shallow depth. If active and passive surface wave data are combined or MAS_RW data are combined from multiple seismic records with different source offsets and receiver gathers, then effective-mode computations are limited to algorithms that assume far-field plane Rayleigh wave propagation. Local search (e.g., linearized matrix inversion methods) or global search methods (neighborhood algorithm; Monte Carlo approaches such as simulated annealing, generic algorithms) are typically used to solve the inverse problem.

The maximum wavelength (λ_{max}) recovered from a surface wave data set is typically used to estimate depth of investigation although a sensitivity analysis of the V_S models would be a more robust means to estimate depth of investigation. For normally dispersive velocity profiles with a gradual increase in V_S with depth, the maximum depth of investigation is on the order of $\lambda_{max}/2$ for both Rayleigh and Love wave dispersion data. For velocity profiles with an abrupt increase in V_S at depth, the maximum depth of investigation is on the order of $\lambda_{max}/3$ for Rayleigh wave dispersion data but less than $\lambda_{max}/3$ for Love wave dispersion data. The depth of investigation can be highly variable for sites with complex velocity structure (including high velocity layers).

As with all surface geophysical methods, the inversion of surface wave dispersion data does not yield a unique V_S model and multiple possible solutions may equally fit the experimental data. Based on experience at other sites, the shear wave velocity models (V_S and layer thicknesses) determined by surface wave testing are within 20% of the velocities and layer thicknesses that would be determined by other seismic methods (Brown, 1998). The average velocity of the upper 30 m (V_{S30}), however, is much more accurate, often to better than 5%, because it is not sensitive to the layering in the model. V_{S30} does not appear to suffer from the non-uniqueness inherent in V_S models derived from surface wave dispersion curves (Martin et al., 2006, Comina et al., 2011). Therefore, V_{S30} is more accurately estimated from the inversion of surface wave dispersion data than the resulting V_S models.

3 FIELD PROCEDURES

Surface wave data were collected along two transects, whose locations were provided by Kleinfelder and confirmed by a company representative. The locations of the transects are shown in Figure 1 and coordinates of the array centers (corresponding to the modeled Vs profiles) and endpoints are provided in Table 1. Two types of surface wave data were acquired at each site: an active-source surface wave array to characterize near-surface velocity structure and a passive-source surface wave array to characterize deeper velocity structure.

The surface wave equipment consisted of four Geometrics Geode signal enhancement seismographs, 4.5 Hz vertical geophones, and seismic cables. The geophone array consisted of 96 live geophones with a nominal spacing of 10 feet, for a total array length of 950 feet. Active MASW sources included 4 lb. and 20 lb. sledgehammers, and a 240 lb. accelerated weight drop (AWD).

Shot points were located between 30 and 300 feet from the end geophone locations and at regular intervals in the interior of the array. At least twenty-four active source locations were occupied with the 4-lb hammer and either the AWD or the 20-lb sledgehammer. Data from the active source impacts were averaged in the field to improve the signal-to-noise ratio. In total this resulted in 48 source locations, and ~720 hammer blows for the project. Ambient noise measurements were made along the passive array for 60 minutes (Array 1) and 53 minutes (Array 2) with a 2 MS sample rate. The field geometry and associated files names were documented in field notes. All field data were saved to hard disk and backed up daily on a remote server.

4 DATA ANALYSIS AND RESULTS

The MASW data were reduced using the software Seismic Pro Surface V10 developed by Geogiga, SeisImager Pick win (Geometrics, Inc.), and multiple in-house utilities for various data extraction and formatting tasks. Because each transect was acquired in a "fully-live" configuration of 96 active receivers, common-midpoint cross-correlation gathers (CMPCC) were generated that organized the common receiver pairs for every shot gather. This allowed for 2-D smooth-model inversion modeling. The surface wave data were modeled using the fundamental mode routine in SeisImager Waves. Data inputs into the modeling software include layer thickness, S-wave velocity, P-wave velocity or Poisson's ratio, and mass density. P-wave velocity and mass density only have a very small influence (i.e., less than 10%) on the S-wave velocity model generated from a surface wave dispersion curve. However, realistic assumptions for P-wave velocity, which is significantly impacted by the location of the saturated zone, and mass density will slightly improve the accuracy of the S-wave velocity model.

During the modeling process an initial velocity model was generated based on provided preliminary CPT summaries. Kleinfelder provided estimates of water table depth (30 feet for Array 1; 16 feet for Array 2), wet and dry unit weights (85 and 115 lbs. per cubic foot, respectively), and Poisson's ratio (0.33). These inputs were used in the initial modeling phase. A first-pass inverse modeling routine was performed, and the results were compared to general characteristics of the dispersion curves. Layer thicknesses were adjusted, and the inversion process repeated until a V_S model was developed with low RMS error between the observed and calculated dispersion curves. Once an acceptable V_S model was developed, layer thicknesses were again adjusted, and the inversion process repeated to compare V_S models with similar RMS error to examine non-uniqueness.

Using the 2-D inversion routine in SeisImager WaveEQ, a 1-D shear-wave velocity profile was generated every 120-feet along each of the two transects shown in Figure 1. The modeled V_S profiles for each transect are presented as Figures 2-3. The resolution decreases gradually with depth due to the loss of sensitivity of the dispersion curve to changes in V_S at greater depth. The V_S profile used to match the field data is provided in tabular form in English units as Tables 2-15. The reported inferred values for P-wave velocity, Poisson's Ratio, and density were calculated based on the shear-wave velocity model results – not direct measurements or lab tests. The initial stage of the modeling process included input parameters provided by Kleinfelder, but these tabulated results show some variation, particularly with respect to density values. The "inferred density" values are based on the relationship between shear-wave velocity and density as described by Boore (2015).

6 CERTIFICATION

All geophysical data, analysis, interpretations, conclusions, and recommendations in this document have been prepared under the supervision of and reviewed by a **GEO***Vision* California Professional Geophysicist.

Prepared by

JB Shawver

9/30/2024

JB Shawver
California Professional Geophysicist, P.Gp. 1058
GEO*Vision* Geophysical Services

Date

This geophysical investigation was conducted under the supervision of a California Professional Geophysicist using industry-standard methods and equipment. A high degree of professionalism was maintained during the project from the field investigation and data acquisition, through data processing interpretation and reporting. Original field data files, field notes and observations, and other pertinent information are maintained in the project files and are available for the client to review for a period of at least one year.

A professional geophysicist's certification of interpreted geophysical conditions comprises a declaration of his/her professional judgment. It does not constitute a warranty or guarantee, expressed or implied, nor does it relieve any other party of its responsibility to abide by contract documents, applicable codes, standards, regulations or ordinances.

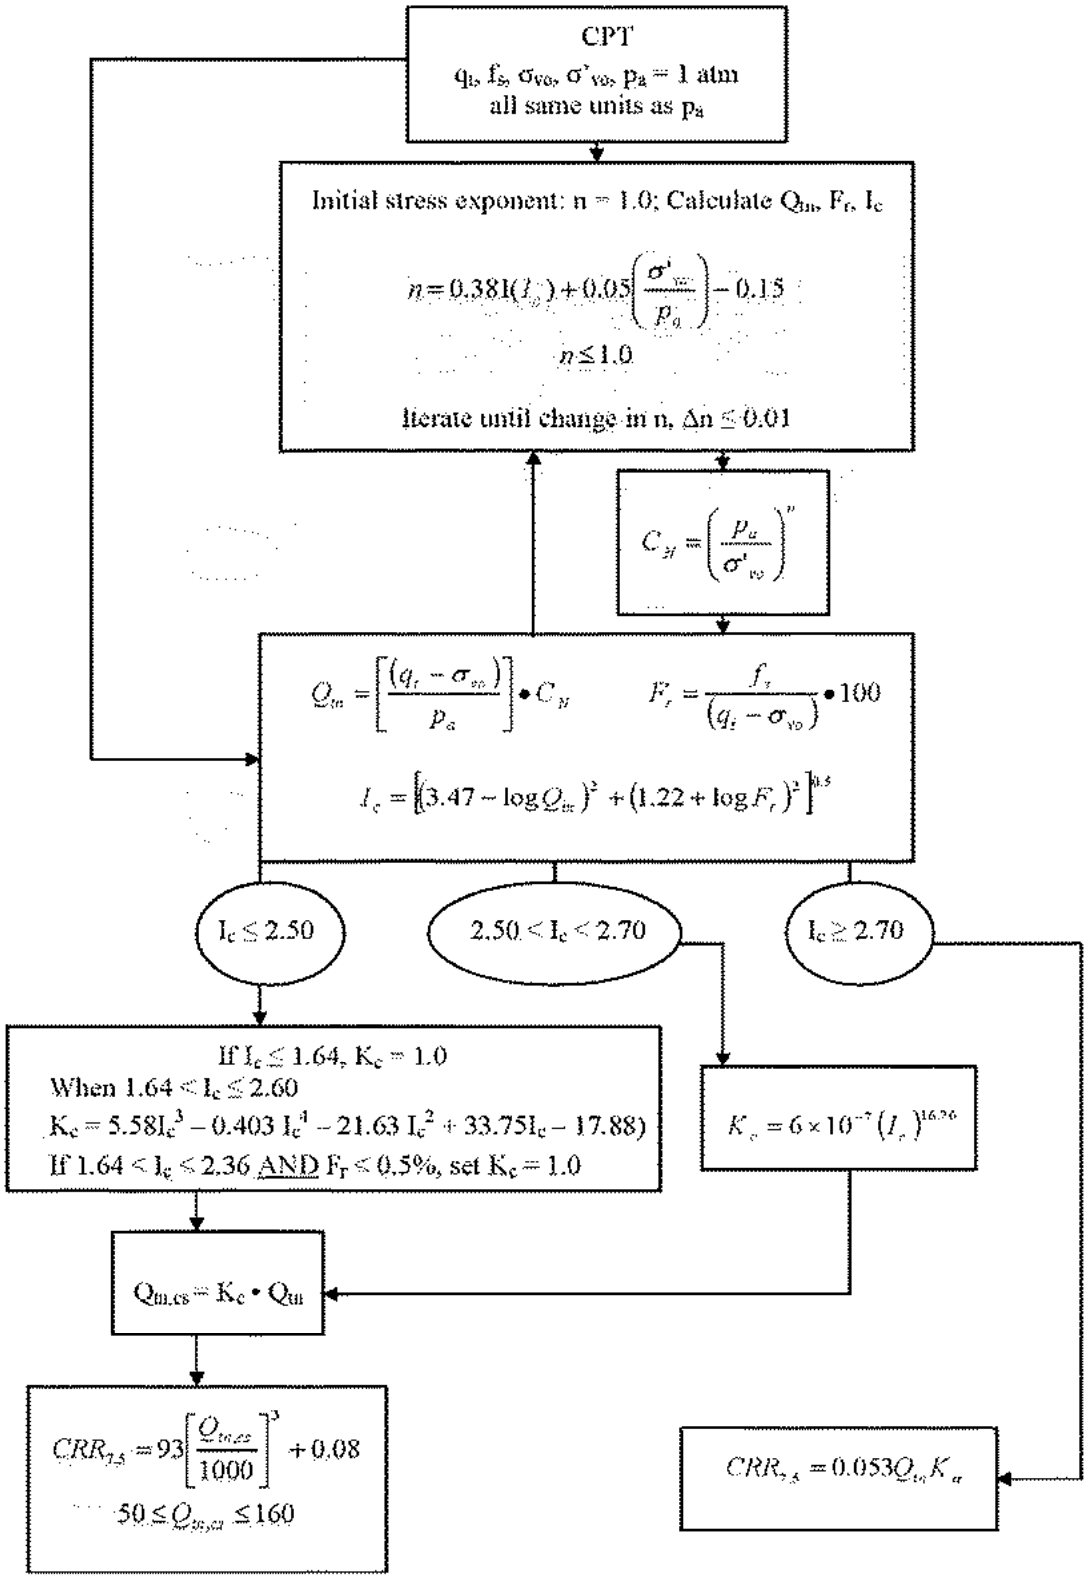
Procedure for the evaluation of soil liquefaction resistance, NCEER (1998)



Calculation of soil resistance against liquefaction is performed according to the Robertson & Wride (1998) procedure. The procedure used in the software, slightly differs from the one originally published in NCEER-97-0022 (Proceedings of the NCEER Workshop on Evaluation of Liquefaction Resistance of Soils). The revised procedure is presented below in the form of a flowchart[1]:

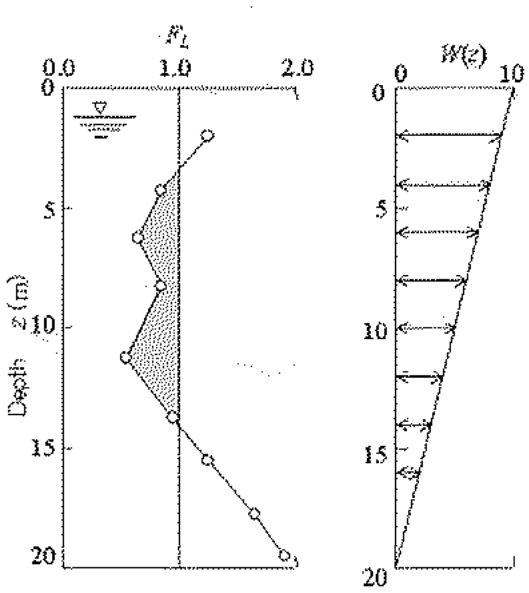
Liquefaction Potential Index (LPI) calculation procedure

Calculation of the Liquefaction Potential Index (LPI) is used to interpret the liquefaction assessment calculations in terms of severity over depth. The calculation procedure is based on the methology developed by Iwasaki (1982) and is adopted by AFPS.



To estimate the severity of liquefaction extent at a given site, LPI is calculated based on the following equation:

$$\mathbf{LPI} = \int_0^{20} (10 - 0{,}5z) \times F_L \times dz$$

where:
F_L = 1 - F.S. when F.S. less than 1
F_L = 0 when F.S. greater than 1
z depth of measurment in meters

Values of LPI range between zero (0) when no test point is characterized as liquefiable and 100 when all points are characterized as susceptible to liquefaction. Iwasaki proposed four (4) discrete categories based on the numeric value of LPI:

- LPI = 0 : Liquefaction risk is very low
- 0 < LPI <= 5 : Liquefaction risk is low
- 5 < LPI <= 15 : Liquefaction risk is high
- LPI > 15 : Liquefaction risk is very high

Graphical presentation of the LPI calculation procedure

Shear-Induced Building Settlement (Ds) calculation procedure

The shear-induced building settlement (Ds) due to liquefaction below the building can be estimated using the relationship developed by Bray and Macedo (2017):

$$Ln(Ds) = c1 + c2 * LBS + 0.58 * Ln\left(Tanh\left(\frac{HL}{6}\right)\right) + 4.59 * Ln(Q) - 0.42 * Ln(Q)^2 - 0.02 * B + 0.84 * Ln(CAVdp) + 0.41 * Ln(Sa1) + \varepsilon$$

where Ds is in the units of mm, c1= -8.35 and c2= 0.072 for LBS ≤ 16, and c1= -7.48 and c2= 0.014 otherwise. Q is the building contact pressure in units of kPa, HL is the cumulative thickness of the liquefiable layers in the units of m, B is the building width in the units of m, CAVdp is a standardized version of the cumulative absolute velocity in the units of g-s, Sa1 is 5%-damped pseudo-acceleration response spectral value at a period of 1 s in the units of g, and ε is a normal random variable with zero mean and 0.50 standard deviation in Ln units. The liquefaction-induced building settlement index (LBS) is:

$$LBS = \sum W * \frac{\varepsilon_{shear}}{z} dz$$

where z (m) is the depth measured from the ground surface > 0, W is a foundation-weighting factor wherein W = 0.0 for z less than Df, which is the embedment depth of the foundation, and W = 1.0 otherwise. The shear strain parameter (ε_shear) is the liquefaction-induced free-field shear strain (in %) estimated using Zhang et al. (2004). It is calculated based on the estimated Dr of the liquefied soil layer and the calculated safety factor against liquefaction triggering (FSL).

APPENDIX E:
TECHNICAL MEMORANDUM

March 3, 2025
Kleinfelder Project No.: 24002328.001A

Mr. Eric Hays
Albert A. Webb Associates
3788 McCray Street
Riverside, California 92506

Subject: Technical Memorandum: Numerical Analysis of Proposed Crossing
San Jacinto Line E Storm Drain
Metropolitan Water District Casa Loma Barrel No. 1 Crossing
San Jacinto, California

Dear Mr. Hays:

Kleinfelder is pleased to present this Technical Memorandum detailing the 3D Numerical Analysis for the proposed crossing of the San Jacinto Line E Storm Drain over the Metropolitan Water District's (MWD) Casa Loma Barrel No. 1. This memorandum is presented as an appendix to this geotechnical report for the subject project. The geotechnical report discusses Kleinfelder's field investigation, laboratory testing, geologic setting and hazards (including faulting and seismicity), ground water discussion, and engineering conclusions and recommendations for various aspects of the project.

We understand that MWD requirements for induced displacement of the Casa Loma Barrel No. 1 are very stringent at ¼-inch per 100 ft tolerances. Given the importance of the Casa Loma Barrel No. 1 and MWD requirements, Kleinfelder has completed numerical modeling of the subsurface conditions and structures using the 3-D finite element program PLAXIS 3D Version 20.04.00.790 published by Bentley. This memorandum includes the results of our calculations, results, and recommendations regarding the proposed MWD Casa Loma Barrel No. 1 crossing structure and associated embankments for the flood-control structures. Discussed in this memorandum are:

- Project Description
- Preliminary Crossing Structure
- Subsurface Conditions & Soil Parameters
- Soil Constitutive Models
- Structural Components & Other Materials
- Model Construction, Boundary Conditions & Meshing
- Loading Conditions
- Model Staging

- Evaluation of Results
- Conclusions and Recommendations

This memorandum is subject to the limitations contained in our geotechnical report.

PROJECT DESCRIPTION

We understand the project involves the design of an approximate 3-mile storm drain channel to be constructed in the City of San Jacinto. The new storm drain channel will be constructed near the existing ground surface and the majority of the alignment consists of earth embankment channels and several reinforced concrete box culverts. Storm water flow is generally south to north and in the northern portion of the alignment the proposed channel terminates at a proposed confluence basin.

In the vicinity of the MWD pipeline (Casa Loma Barrel No. 1), the channel transitions to a concrete channel with an approximate 160-ft base width with side slopes inclined about 15 to 17:1 (H:V). At the proposed crossing, the proposed channel and embankment cross-section is approximately 560-ft wide. A preliminary plan including contours of the proposed embankments and channel and a cross-section at the MWD pipeline crossing, dated 10/15/24 were provided by Albert A Webb Associates (Webb), shown in in Attachment A as Figure E1. CAD files and data used to construct these plans were also provided by Webb and utilized to construct surfaces for the 3D modeling.

Due to the low cover present over the MWD pipeline, the proposed construction also includes a bridge structure to facilitate possible equipment and vehicle loads, using a transfer slab on supporting foundations to limit induced displacement and stresses in the MWD pipeline. Two preliminary options were considered for the crossing structure: Option 1 - Shallow Spread Footings, and Option 2 – Deep Foundations consisting of cast-in-drilled hole (CIDH) shafts. Kleinfelder is the structural engineer for this proposed crossing structure and provided the structural loading and was consulted in selection and modeling of the structural elements, as discussed in later sections of this memorandum.

PRELIMINARY CROSSING STRUCTURE

Two options were evaluated to support the proposed crossing structure: 1) a shallow foundation option and 2) a deep foundation option. Preliminary modeling of both solutions was conducted to evaluate the feasibility of the proposed construction. However, after preliminary modeling showed that the controlling induced displacement of the pipeline was primarily controlled by the embankment fills and flood loading, the pile option did not appear to be necessary for the crossing. In addition, difficult construction conditions, economic feasibility and other considerations have moved the preferred solution towards the shallow foundation option. As such, this memorandum focuses on the shallow foundation model development and results.

Additional discussion of the two options and selection considerations can be found in this geotechnical report and our separate structural report (Kleinfelder, 2025).

© 2025 Kleinfelder

SUBSURFACE CONDITIONS & SOIL PARAMETERS

We reviewed the geotechnical borings, laboratory test data, and other geotechnical analyses completed by Kleinfelder for the project for relevant information to define the mechanical behavior, including correlations to stiffness and strength characteristics. The various correlations and select laboratory test results were plotted in depth profiles to evaluate and select the relevant parameters for the proposed soil constitutive models. Plots of the profiles are provided in Figures E2 to E5. Based on elevation data provided by Webb, the approximate average ground surface in the vicinity is about EL. 1449.5 ft. For the purposes of plotting the soil parameters versus elevation, we have used a ground surface of EL. 1450 ft. Groundwater levels appear to vary significantly throughout the region with potential for different regimes due to faulting and other geologic conditions, see the discussion in our geotechnical report. In the area of the proposed crossing, the groundwater elevations noted in our borings range from approximately 34.5 ft to 16.5 ft below ground surface. For the purposes of our analyses, we have assumed that the groundwater depth of 16.5 ft or EL. 1433.5 ft.

The soils logged in the borings near the proposed crossing and indicated by the soil behavior type CPT soil behavior type are predominantly silty sand to sandy silt with some interbedded silt and clay soils. Due to the non-plastic to low plasticity and interbedded deposition we expect that the soils will exhibit drained behavior and that if excess pore-pressures are produced they will likely dissipate within the time frame of the expected loading conditions. As such the model behavior of the soils is defined as drained and the effects of excess pore-pressure neglected.

After discussions with MWD, additional geophysical testing was conducted to measure the shear-wave velocity (V_S) and therefore, the stiffness of the subsurface conditions. The report from GEOVision detailing the data collection and processing is Appendix C of this geotechnical report. The average V_S profiles of the two arrays, one conducted north and one south of the MWD pipeline are shown on the soil property figures. The elastic modulus (E) calculated from the shear-wave velocity data using the relationship $G_{max} = \rho V_S^2$, where G_{max} is the maximum or low-shear strain (< 10^{-4} to 10^{-3} %) shear modulus and ρ is the soil mass density and Poisson's ratio derived from the soil strength. Additionally, to adjusted G_{max} from low shear strains (< 10^{-4} to 10^{-3} %) to strain magnitudes expected in the modeling (~0.1 to 1%), the V_S was divided by a factor of either 2 or 3 to calculate an implied G and subsequent E moduli and provide a reference for the values used in the constitutive models. Plots of these implied elastic modulus are shown on Figures E4a and E4b.

SOIL CONSTITUTIVE MODELS

The constitutive models define the stress-strain behavior of the soil. The primary characteristics considered when selecting the soil constitutive model, included the ability of the constitutive model to:

1. provide a reasonable fit to the expected stress-strain behavior.
2. capture the depth/stress dependent stiffness characteristics evidenced by the in-situ and V_S data.
3. provide both unload and reload moduli.

Within PLAXIS, there are several constitutive models available. However, two were considered as part of this study: 1) the linear-elastic perfectly plastic (Mohr-Coulomb) model and 2) the hardening soil (Hardening) model. Each model requires several inputs that define the behavior, with the primary being

© 2025 Kleinfelder

the soil strength parameters (c = cohesion, ϕ = friction angle) and stiffness parameters (varies dependent on the model). Both models were considered for use in the 3D model.

The Mohr-Coulomb model presents the simpler model stiffness inputs with the stiffness behavior defined by the elastic modulus (E) and Poisson's Ratio (ν). As the elastic modulus does change with shear strain, care must be taken in selected this parameter for the appropriate stress/strain levels expected in the modeling. An option to vary the stiffness with depth/elevation is provided in PLAXIS and was utilized to better match the observed variation in stiffness with depth. One drawback of the Mohr-Coulomb model as implemented in PLAXIS, is that the definition of an unload/reload modulus is not allowed. The Mohr-Coulomb was utilized for the embankment fills, geofoam, and concrete volumes as discussed further below.

The Hardening model is also a Mohr-Coulomb model, in that the strength behavior is governed by Mohr-Coulomb strength envelope. However, the model is different in that it incorporates hardening plasticity (e.g. decreasing stiffness with plastic straining) (Shanz 1998). This allows for the modeling of non-linear stress-strain behavior that is observed in soil laboratory testing, often called "hyperbolic soil" behavior and implemented by Duncan and Chang (1970). Shanz et. al. (1998 and 1999) built on the Duncan and Chang (1970) framework to make the required input parameters more easily defined and related to conventional geotechnical engineering properties, as well as more technical aspects that we would refer the reader to either the PLAXIS, FLAC, or source papers for more information. Specific to this study, the hardening model allows for a stress dependent stiffness definition and the non-linear hyperbolic stress-strain behavior observed in the laboratory testing. The implementation of this model also allows for the definition of an unload/reload modulus making the model well suited for excavation analyses. The Hardening model is used for the naturally deposited Sandy SILT to Silty SAND soils observed in the geotechnical investigation.

As a summary of the similarities and differences between the Mohr-Coulomb and Hardening model:

Model Aspect	Mohr-Coulomb	Hardening
Strength Envelope	Mohr-Coulomb	Mohr-Coulomb
Stiffness Dependency	Yes, through depth.	Yes, through stress.
Stress-Strain Behavior	Perfectly Elastic, Perfectly Plastic	Hyperbolic, Perfectly Plastic
Unload/Reload Modulus	No	Yes

Table E1 shows the input various input parameters selected for the models. As the goal of this study is to evaluate the induced displacements in the MWD pipeline, particular care was taken when selecting the various input parameters related to the stiffness of the soil models. Figure E6 is included to help show how the Hardening model input stiffness parameters relate to the stress-strain behavior. The stress-dependent E_{50} stiffness computed per Eq. 151 of the PLAXIS manual is plotted on Figure E4a. The initial modulus (E_i) shown on Figure E6 is also plotted on Figure E4a for comparison purposes computation per Eq. 136 of the PLAXIS manual. The stress-dependent elastic unload/reload modulus (E_{ur}) is likewise computed per Eq. 139 of the PLAXIS manual and plotted on Figure E4b. For comparison with the V_S data, the E_{50} represents an approximate dividing factor of 3.5 to the measured V_S data. Likewise, the E_i and E_{ur} for comparison are an approximate dividing factor of 2.65 to the measured V_S data.

© 2025 Kleinfelder

Table E1: Soil Constitutive Model Parameters for Silty SAND to Sandy SILT Soils

Parameter	Description	Hardening
E_{50}^{ref} (ksf)	Reference Secant Elastic Modulus at 50% of Strength Failure	180
E_{oed}^{ref} (ksf)	Reference Oedometer Modulus at 50% of Strength Failure	200
E_{ur}^{ref} (ksf)	Reference Unload/Reload Modulus at 50% of Strength Failure	600
m	Power for Stress Dependency of Stiffness	0.8
P_{ref} (psf)	Reference Stress for Stiffness (Used Atmospheric Pressure)	2116
K_0^{nc}	At-Rest Earth Pressure Coefficient for Normal Consolidation (Based on the Design Friction Angle)	0.5
R_f	Failure Ratio (Ratio of q_a / q_f in Figure E6)	0.9
ν_{ur}	Poisson's Ratio for Unload/Reload Modulus	0.2
ν	Poisson's Ratio (Based on the Design Friction Angle)	0.33
γ_{unsat} (pcf)	Dry Unit Weight	85
γ_{sat} (pcf)	Saturated Unit Weight	115
c (psf)	Cohesion	50
ϕ (deg)	Friction Angle	30
ψ (deg)	Dilatancy Angle	0
σ_t (psf)	Tensile Strength	0

Laboratory testing conducted on select soil samples were digitized and imported into PLAXIS for use in the soil test module, which simulates common types of laboratory tests in the finite element framework, to assist with the calibration of the soil constitutive model parameters and stress-strain behavior. Figures E7 to E9 show the results of the laboratory direct simple shear tests with the Hardening model. For reference, the equivalent elastic modulus calculated from the V_S /2 data is included on the figures.

The final selected parameters were selected to present a reasonable match to the shape and behavior of the laboratory testing, but the soil stiffnesses relied upon the correlations and Vs measurements as the soil samples used for laboratory testing were taken from thick-walled SPT samplers and were likely subjected to sample disturbance than would particularly affect the small stiffness behavior during laboratory testing. Otherwise, the soil parameters selected present a reasonable match to the laboratory testing based on our professional experience and judgment.

STRUCTURAL COMPONENTS & OTHER MATERIALS

The structural components modeled included the MWD pipeline and proposed crossing structure shallow footings, both of which are concrete. In discussion with MWD and Kleinfelder's structural engineering team, we understand that the compressive strength of the concrete to be 3000 psi and 3600 psi for each component, respectively. The compressive strengths are not directly used as inputs to the selected linear-elastic constitutive models and instead used to calculate the elastic modulus (E_C) following Eq. 19.2.2.1.b of ACI 318-19. To account for possible cracking, a 50% reduction was applied to the calculated E_C. Other necessary inputs include, Poisson's ratio was taken as 0.2, and unit weight taken as 150 pcf. Sensitivity analyses were performed for the concrete constitutive model parameters and no significant effect on the model results were found, likely due to the much larger relative stiffness of the concrete compared to the soils.

© 2025 Kleinfelder

The thickness and dimensions of the MWD pipeline and proposed concrete footings were provided by information from Webb and Kleinfelder's structural team. The preliminary cross section of the MWD pipe and proposed shallow foundation concept used to construction the PLAXIS model are shown in Figure E10. The MWD pipeline was modeled as "plate" or shell elements with virtual thickness of 1 ft and necessary simplification to a circular section was made to model the pipeline. The MWD pipeline invert was placed at EL. 1432.85. The concrete footings were modeled using volume elements like the soil materials. The modeling including 1.5H:1V excavation extents anticipated during construction to install the footings. We understand that some minor revisions to the footing shape and possible excavation extents (i.e. using soil forming to reduce the excavation) will be incorporated into the final design to facilitate construction formwork and reduce the need for lateral bracing that may impact the MWD pipeline. Details and discussion of the structural analysis can be found in Kleinfelder's structural report (Kleinfelder, 2025). The proposed changes have been discussed with the project team and are not expected to impact the results of the PLAXIS modeling as 1) only small changes are expected to the footing loads and footing concrete volumes, and 2) the model results controlling the displacement are drive by the embankment fills and the 100-yr flood loads (discussed further in later sections).

Interface elements were included in the model to control the normal and shear behavior between the concrete footing and the adjacent soils, which allows for non-rigid connections between these elements. The interface parameters automatically derived based on the adjacent material with a manual input factor to reduce the shear strength of the soil, which should be determined based on the interfacing materials. Interface friction angles for fine sandy silt (non-plastic silt) presented in the NAVFAC (1982a) range from 17 to 19 degrees. Using an interface friction angle of 18 degrees and 30 degrees soil friction angle, this results in a reduction factor from the soil strength to soil-concrete interface strength of 0.56. This factor was applied for all soil materials.

In addition to the structural elements, the modeling utilized volume elements to represent the various embankment fills and other materials proposed materials needed to maintain the induced displacement criterion for the MWD pipeline. These consist of geofoam proposed to be placed below the crossing structure slab, lightweight flowable fill, consisting of lightweight cellular concrete, proposed as the primary fill material within the specified distance from the MWD pipeline alignment, and structural fill, consisting of soil material, for the remaining areas outside the crossing and assumed to consist of properly placed and compaction soils similar to the on-site soils. The Mohr-Coulomb constitutive model was selected for these materials as 1) significant unload/reload behavior is not expected (e.g. excavations) in these materials and 2) in-situ and laboratory testing was not available to confirm the stress-dependent behavior, nor that non-linear behavior exhibited by the Hardening model would be appropriate for these materials, and 3) the primary purpose of the fill volumes is to more accurately represent the added weight and resultant stresses on the model.

The selected input parameters from available literature are presented in Table E2.

Table E2: Fill Material Constitutive Model Parameters

Parameter	Description	Structural Fill (Soil Material)	Lightweight Flowable Fill (LCC)[1]	EPS Geofoam (Underslab Fill)[2]
E (ksf)	Elastic Modulus	500	2140	216
v	Poisson's Ratio (Based on the Design Friction Angle)	0.33	0.3	0.15
γ_{unsat} (pcf)	Dry Unit Weight	127.5	30	2.4
γ_{sat} (pcf)	Saturated Unit Weight	127.5	30	2.4
c (psf)	Cohesion	50	5	1080
ϕ (deg)	Friction Angle	30	34	0
ψ (deg)	Dilatancy Angle	0		
σ_t (psf)	Tensile Strength	0		

1. LCC = Lightweight Cellular Concrete, parameters estimated from Legatski (1994) and Tiwari, et. al. (2017)
2. Parameters taken as EPS-39 Geofoam.

MODEL CONSTRUCTION, BOUNDARY CONDITIONS & MESHING

Model boundary conditions for static analyses were not altered from the default PLAXIS conditions, which consist of fixed displacements in all directions for the bottom of the model, fixed displacements normal to the lateral extents, and the surface of the model is free in all directions. The horizontal boundaries were set such that along the pipeline (the approximate model x-direction) the model extended about 55 ft beyond the extents of the proposed fills. Roughly perpendicular to the pipeline (the approximate model y-direction) the model was extended to about 70 ft from the closet distance to the centerline of the pipe alignment. Based on our review of the induced displacements and stresses due to the fills and loads, the model boundary conditions appear to be at a sufficient distance to have not significantly influenced the model results in the vicinity of the pipeline (the area of interest).

Geometric objects were constructed in PLAXIS to represent the embankment fills, pipeline, footings, and excavations. The embankment point cloud data was provided in AutoCAD files provided by Webb. The point cloud data was imported using the related feature in PLAXIS, which discretizes the data into a triangular irregular network (TIN) to provide an elevation surface. This surface was then laid on the average approximate ground surface within the model boundaries to generate the fill volumes for the embankments and channel alignment. The use of the average approximate ground surface was a necessary simplification because of issues with the merging of the existing and proposed surfaces caused by floating point precision of intersecting planes. Based on our review of the existing elevation data, we expect that this necessary simplification should have overall minor impact on the results of the modeling as the existing surface was relatively flat, particularly in the area around the pipeline, and by using the average, the relative ± elevation differences should be roughly offsetting. Other geometric objects were constructed in the model using the simpler polygonal tools in PLAXIS to match the proposed structural footing and excavation dimensions and elevations and existing pipeline alignment.

Meshing of the model was completed using PLAXIS's internal meshing routines and control parameters prescribed such that elements around areas of interest (e.g. the footings, excavations, and pipeline), were approximately 2 ft in size. Elements away from the areas of interest were gradually increased in size by the PLAXIS routines to allow for more efficient computations. Figure E11 shows a plan view of the model

© 2025 Kleinfelder

mesh. The meshed geometry was evaluated to ensure the meshing routines produced reasonably sized and shaped elements. Some small and elongated elements were generated but were deemed acceptable as they were generally located towards the model boundaries and edges of the fills and not expected to significantly impact the results.

LOADING CONDITIONS

Several loading conditions were considered during our evaluation and were provided by Kleinfelder's structural team, including:

- Water Load in the Pipe (Initializing Condition)
- Dead Loads of the Bridge Slab
- Water Load on the Bridge Slab & Modeled Channel
- Live Loads of Equipment on the Bridge Slab

We understand from discussion with MWD that this portion of the pipeline alignment the water inside the pipe is gravity flowing. Therefore, the water load was included in the model to better reflect the actual conditions. The water load was incorporated as a volume material with the parameters shown in Table E3 to better represent the weight and stress distribution to the model. An interface was included between the pipe and the elements to eliminate rigid connections between the water and pipe elements.

Table E3: Water Constitutive Model Parameters

Parameter	Description	Water
K (ksf)	Bulk Modulus	43,170
v	Poisson's Ratio (Based on the Design Friction Angle)	0.499
γ (pcf)	Unit Weight	62.4
Su (psf)	Shear Strength[1]	5
σ_t (psf)	Tensile Strength	0

1. A minimal amount of shear strength was given to the water material to allow the model to converge.

More detailed discussion of the loads applied by the proposed crossing structure can be found in Kleinfelder's structural report (Kleinfelder, 2025). We note that minor differences in the applied slab dead load (~3%) shown in our structural report due to the slight changes in the footing geometry, extending the crossing slab. However, we don't anticipate that these will present significant changes to the PLAXIS model results as the worst-case displacement conditions are controlled by the embankment placement and 100-yr flood loading. The 100-yr flood elevation has not changed and due to the inclusion of the surface load, the overall model loading in this condition would not change. Table E4 shows the loading conditions applied to the PLAXIS model. Based on the rough profile dimensions and elevations show on Figure E1, we anticipate that the anticipated 100-yr flood load and embankment loads using light weight fill will add stresses at the existing ground surface in the range 200 to 300 psf. These loading conditions were incorporated into our model staging discussed further below.

© 2025 Kleinfelder

Table E4: Footing Loads from Transfer Slab

Loading Condition	Description	Applied Load
Dead	Dead Load of Slab	2.65 k/ft
Water[1]	100-yr Flood Load on Slab	3.5 k/ft
Live Load	Excavator Transverse[2,3]	5.54 k/ft
	Excavator Longitudinal[2,4]	36.47 k

1. The 100-yr flood load was also included as surface load applied across the proposed channel formed by the embankments. The surface load utilized PLAXIS features to apply a 62.4 pcf vertical load increment from the reference elevation of 1453.47 ft (the provided 100-yr flood elevation) at the MWD alignment.
2. When the live loads were applied, they were only applied to the upstream crossing structure footing.
3. Transverse load was applied of a 13.17 ft length and placed in three locations along the bridge (left side, centered, and right side), as provided by the structural team.
4. Longitudinal load was applied as a point load at three locations along the bridge (left side, centered, and right side), as provided by the structural team.

MODEL STAGING

Once the constitutive models for the various components were defined and the geometries created, the model staging and sequencing were developed in PLAXIS. Construction staging was utilized in PLAXIS to initiate existing stresses and strains within the model, including the existing MWD pipeline. This was followed by staging of excavations, footing sequencing, backfilling, and various loading conditions. The construction staging followed these steps:

- Step 0: Initial Phase - This step is used to initiate stresses into the model and displacements/strains are reset following this step.
    - 0.a: PLAXIS K_0 Routine & Gravity Loading
    - 0.b: Activation of MWD Pipe – the MWD pipe is “wished” into place and external interface is activated.
    - 0.c: Add Water Inside the MWD Pipe – the water is “wished” into place and interface activated.
- Step 1: Excavate & Place Footings – This represents construction sequencing used to limit the uplift of the MWD pipe. The crossing structure is divided into 1/3 sections and excavation and placing of the footings is done on both side of the pipe simultaneously to limit lateral displacements of the MWD pipe. See the conclusions and recommendations section for more discussion.
    - 1.a: Excavate Center 1/3
    - 1.b: Construct Center 1/3 Footing
    - 1.c: Excavate Left 1/3
    - 1.d: Construct Left 1/3 Footing
    - 1.e: Excavate Right 1/3
    - 1.f: Construct Right 1/3 Footing
- Step 2: Backfill Footings – This represents the backfilling of the constructed footings. The crossing structure will be backfilled with medium weight flowable fill/LCC to limit induced vibrations that

© 2025 Kleinfelder

may impact the MWD pipeline. The structural design of the backfill requires that the LCC has similar unit weight and strengths to the existing soils for overturning and confinement. Therefore, the model sequencing backfills with the existing soil.

- Step 3: Place Channel Embankments – This represents the fill placement to construct the channel embankments.
- Step 4: Apply Dead Loads from Slab – This represents the construction of the transfer slab.
- Step 5: Apply Various Loads – This represents the various loading conditions applied to the footings by the loads on the transfer slab and the 100-yr flood load. We note that these loading conditions are not expected to occur at the same time and are therefore branches in the analysis tree.
    - 5.a: 100-yr Flood Load
        - 5.a.1: Remove 100-yr Flood Load
    - 5.b: Transverse Excavator on Left
    - 5.c: Transverse Excavator on Center
    - 5.d: Transverse Excavator on Right
    - 5.e: Longitudinal Excavator on Left
    - 5.f: Longitudinal Excavator on Center
    - 5.g: Longitudinal Excavator on Right

Figures E12 to E30 show a view of the model for each of these steps.

EVALUATION OF RESULTS

Based on discussions with MWD, we understand that the following results are desired to evaluate the impact of the proposed construction on the MWD pipeline:

- Vertical Displacement Profiles
- Lateral Displacements
- Longitudinal Stress Profiles (Extreme Fiber)
- Hoop Stress Profiles (Extreme Fiber)

The requested results are presented for select load cases in the figures outlined in Table E5.

Table E5: Summary of Profile Results

Modeling Stage	Results Shown	Figure #
Step 1: Full Length Excavation	Vertical Displacement (Crown & Invert)	E31
Step 1a-f: Staged Excavations	Vertical Displacement (Invert Comparison)	E32
	Vertical Displacement (Crown & Invert at Each Stage)	E33 to E38
	Lateral Displacement (Spring Lines at Each Stage)	E39

© 2025 Kleinfelder

Modeling Stage	Results Shown	Figure #
Step 3: Place Channel Embankments	Vertical Displacement – Full Weight vs Light Weight Comparison (Crown & Invert)	E40
	Lateral Displacement (Spring Lines)	E41
Step 4-5a.1: 100-yr Flood Loading	Vertical Displacement (Crown Comparison)	E42
	Vertical Displacement (Crown & Invert)	E43 to E45
	Lateral Displacement (Spring Lines)	E46
Step 5.b to 5.g: Various Equipment Load Cases	Vertical Displacement (Crown Comparison)	E47
PLAXIS Pipe Axis and Stress Derivation	N/A	E48
Step 1.e, 3, 5.a	Longitudinal Stress (Crown)	E49 to E51
	Longitudinal Stress (Invert)	E52 to E54
	Hoop Stress (Crown)	E55 to E57
	Hoop Stress (Invert)	E58 to E60
	Hoop Stress (Downstream Spring Line)	E61 to E63
	Hoop Stress (Upstream Spring Line)	E64 to E66

Excavations for Footings

Initial construction sequencing considered the potential that footing excavations may be made on one side of the pipe then the other. Modeling results of this scenario showed that the lateral induced displacement from excavating on one side then the other exceeded the allowed tolerances before combining with the potential uplift. Therefore, during conversations with the design team and contractors the limitation of simultaneous excavation was discussed and determined that simultaneous excavation would be possible and not overly burdensome to the construction effort and additional refinements and results for the "unbalance excavation" scenario are not included.

Figure E31 shows the vertical displacement results for the full-length excavation. The results indicate that the Hardening model exceeds the ¼ inch per 100-ft differential tolerance. As such, additional consideration was given to sequencing the excavation and construction of the footing into 1/3 lengths where a portion of the footing is excavated then constructed before additional excavation is completed. Figure E32 shows the results of the 1/3-staging sequence for the pipe invert, which shows the higher vertical displacements. The full-length excavation is shown for reference.

Figures E33 to E38 show the results of the vertical displacement results for the staged excavations (Step 1a to 1f, respectively). The results are shown for the crown and invert to evaluate the potential squashing

© 2025 Kleinfelder

of the pipe. Again, the full-length excavation is shown for reference. Vertical displacement results after backfilling of the footing show that the uplift of the pipe is reversed and the displacements nearly return to zero, showing some pipe settlement due to the added footing weight.

Figure E39 shows the resulting lateral displacement profiles at the pipe spring lines for each construction sequencing step. The results from the full-length excavation are shown for reference. We note that only minor changes were observed between the excavation and footing placement, so many of the profiles are overlapped. Maximum estimated lateral displacements are on the order of 0.07 inches.

Full Weight vs Light Weight Fill

Initial considerations for the proposed embankments revolved around the embankment material. Figure E40 shows the vertical displacement results using full weight fill, consisting of soil structural fill as defined in our geotechnical report, for the full extents of the model domain at both the pipe invert and crown. Maximum predicted displacements are on the order of 5/8 to 3/4 inches with differentials over a 100 ft span of up to about 5/8 inch, which exceed the acceptable tolerances. Therefore, lightweight flowable fill will be required in the proximity of the MWD pipeline.

Based on the induced displacements of the full weight fill, the lightweight material's unit weight was selected to be 30 pcf. We anticipate that the most readily available material is a lightweight cellular concrete (LCC) and developed the constitutive model parameters based on this material, as discussed previously. We selected a distance of 50 feet from the edge of the MWD pipe alignment as the area in which the LCC will be required. This was a combination of engineering judgement and to provide adequate distance such that vibratory compaction equipment needed to place and compact structural fill would present minimal impact to the pipe. Figure E40 also shows the vertical displacement results using the lightweight fill, which met the ¼-inch over 100 ft criteria.

Figure E41 shows the lateral displacement results at the pipe spring lines using the full weight and light weight fill.

Dead, Live & 100-yr Flood Loads

Figure E42 shows the progression from Step 3 with the lightweight fill to Step 5.a.1, which follows the possible loading sequence of a 100-yr flood load being applied after construction of the crossing structure. For clarity, these figures are shown just for the pipe crown, which shows more displacement (dashed lines in Figure E40). The peak displacement induced by the 100-yr flood load is about 0.4 inches. The unloading phase indicates that no permanent displacement of the pipe is expected after the 100-yr flood loading. This is likely due to the low stresses added stresses during the peak flood load, about 250 psf based on the bridge and flood elevations. This load added stress results in only small strain development in the soil constitutive models, where the loading modulus of the Hardening model is closer to the initial elastic modulus (Ei) in Figure E4a. Inspection of the Ei in Figure E4a and the unload/reload modulus (Eur) in Figure E4b indicates that these moduli are similar for most of the profile depth. Therefore, it appears that the results seen in Figure E42 are in-line with the expected model behavior.

Figures E43 to E45 show the results for both the invert and crown in Steps 4, 5.a, and 5.a.1, respectively, to evaluate the pipe squashing. Figure E46 shows the results lateral displacements for the various steps during the 100-yr flood sequence at the pipe spring lines.

© 2025 Kleinfelder

Figures E47 show the vertical displacement results for the remaining equipment load cases, including Steps 3 and 4 for reference at the pipe crown. We note that the induced vertical displacements from the equipment loads are very similar to the slab dead load and each other and are overlapping on the presented plots. Additionally, the displacements are much less than the peak displacement exhibited by the 100-yr flood load. Therefore, for simplicity we have not included the lateral displacement or pipe crown vs invert results.

The displacement results show that the ¼-inch over 100 ft criteria are met, provided the assumptions regarding the proposed materials, extents, and sequencing are met.

Stress Profiles

We understand that MWD wishes to evaluate the predicted stresses from the explicit modeling of the pipe. The results provided by PLAXIS for shell elements are the axial, shear, and bending moment forces per unit length along three local axes. The local axes of the pipe shell element correspond with Axis 1 – Longitudinal, Axis 2 – Hoop, Axis 3 – Perpendicular to the Shell. Figure E48a shows these local axes from the model. These results were used in conjunction with the element thickness to calculate the various requested stresses in the pipe following bending stress equations, shown in Figure E48b. Based on these calculations, at any given profile (e.g. the longitudinal stresses at the pipe crown) there are three possible stresses that can be reported:

- Axial Stress
- Combined Stress (Axial + Bending)
- Combined Stress (Axial - Bending)

As the MWD Casa Loma Barrel is constructed of concrete, we have focused the results on the "tension side" combined stress (axial + bending) as this will present the more positive or more tensile stresses in the pipe elements at the subject location.

To emphasize the model conditions expected to have the most significant impact on pipe stresses due to induced displacements, we present the stress results for Steps 1.e, 3, and 5.a. As the pipe stresses are initialized during Step 0.c, but not reset, each plot contains the initial stress after adding the water into the pipe to evaluate the induced changes at each stage.

Figures E49 to E54 show the longitudinal fiber stresses for each selected step at the invert and crown model results. Likewise, Figures E55 to E60 show the hoop fiber stresses at the invert and crown, and Figures E61 to E66 shows the hoop fiber stresses at the pipe spring lines. We note that some chattering is present in the stress data. Based on a response from PLAXIS support, they believe this is an artifact caused by the extrapolation of the stress/force data from the internal gaussian stress points to the points at which the data is extracted (generally at the nodes of the elements). PLAXIS stated that artifact would not affect the estimated pipe deflections. It is possible that reduction of the pipe element mesh may reduce this noise but would likely still be present to some degree due to the triangular elements. Based on the subsequent discussion with MWD, it was decided not to further refine the pipe mesh.

© 2025 Kleinfelder

CONCLUSIONS AND RECOMMENDATIONS

Based on the analyses completed, the proposed flood channel and associated embankments/crossing structure are expected to induce less than the required ¼" inch over 100 ft displacement tolerance required by MWD, provided the recommendations contained in this memorandum and geotechnical report, and Kleinfelder's structural engineering report are followed. The key recommendations and assumptions utilized in the modeling that must be implemented in the design and construction of the crossing are:

- Excavations will not be completed at a time when MWD has emptied the pipeline (i.e. it is not in-service).
- The crossing structure footings are constructed following the 1/3 sequence of excavation and footing placement.
    - Excavation of the subsequent 1/3 shall not progress until the footing for the previous 1/3 is in-place.
    - Excavation slopes and benches shall not be flatter than 1.5H:1V.
- Excavation and footing construction sequence shall be completed simultaneously on the upstream and downstream sides of the MWD pipeline. Simultaneously shall mean:
    - Elevations in excavations on either side shall not be more than 1 ft different.
    - The concrete footings shall be poured on both sides at the same time.
- Excavations shall not be backfilled until the full footing construction sequence is completed.
    - Backfill will consist of a flowable fill material (e.g. LCC) with a unit weight of approximately 85 pcf which does not require high vibration compactor equipment during placement.
    - Backfill shall be completed simultaneously on the upstream and downstream sides of the MWD pipeline. Simultaneously shall mean elevations of the backfill on each side shall not be more than 1 ft different.
- Lightweight flowable fill shall be used for embankments within 50 ft from the edge of the MWD pipe. Embankment fill shall consist of lightweight flowable fill material (e.g. LCC) not to exceed a unit weight of 30 pcf and does not require compaction to limit vibration impacts.
- Embankment fill shall be placed such that the elevation difference across (upstream to downstream sides) the MWD pipe is not greater than 1 ft at any time until final grades are established.
- The channel section shall limit the 100-yr flood event to a peak water elevation of 1453.47 ft.

Additional construction considerations, such as subgrade preparation for footings and fill placement are discussed in the geotechnical report.

LIMITATIONS

Kleinfelder has been provided information by and discussed the modeling evaluation with representatives of MWD, Webb, and Alabasi (the contractor), which were used in developing our model geometries, parameters, sequencing and assumptions. The results of this evaluations are in part reliant on provided

© 2025 Kleinfelder

information and feasibility of the construction limitations. Actual geometries and conditions will be different than those evaluated and engineering judgement is necessary to interpret and apply the analysis results to the realities of the project conditions. Kleinfelder should be notified of any changed conditions or plans that are in conflict with the assumptions and project understanding detailed in this analysis. Failure to notify Kleinfelder of changes and, therefore, inappropriately applying our conclusions and recommendations to the project are at the responsibility of those entities.

This technical memorandum is also subject to the limitations contained within our geotechnical report prepared for the project.

Respectfully submitted,

STRUCTURES REPORT

February 14, 2025
Kleinfelder Project No.: 24002328.001A

Mr. Eric Hays
Albert A. Webb Associates
3788 McCray Street
Riverside, California 92506

Subject: Structural Design of Line E Channel Crossing over MWD Casa Loma Barrel No. 1
San Jacinto, California

Introduction

This report discusses the development of a preliminary crossing design for the proposed Line E channel over the existing Casa Loma Barrel No.1 Siphon operated by the Metropolitan Water District (MWD). This report discusses the concepts considered for this crossing and why one concept was ultimately chosen over the other. Additionally, this report presents the design criteria, plans for the preliminary crossing and the preliminary design calculations. Finally, construction restrictions and a preliminary construction work plan are discussed.

Crossing Concepts

Two concepts were developed for the proposed crossing. Both concepts support a reinforced concrete "relieving slab" isolated from the soil above the siphon by a 6-inch layer of polystyrene foam. The first concept is supported on shallow spread footing foundations, and the second concept is supported on cast-in-drilled-hole (CIDH) concrete piles. Preliminary geometries and dimensions for both concepts are presented in Attachment 1.

Concept 1: Relieving Slab on Spread Footings

This concept is more consistent with the MWD Detail SK-1 from the *Guidelines for Improvements and Construction Projects Proposed in the Area of Metropolitan's Facilities and Right-of-Way*. An advantage of this concept is that it simplifies the settlement analysis by limiting the effects of the crossing structure on the global settlement behavior. The primary drawback of this concept is that, due to the quality of the native soil, the local settlement beneath the crossing is higher than in Concept 2. One mitigation method for this issue is to stage the construction to allow foundation settlement due to backfill and dead load to

© 2024 Kleinfelder

KLEINFELDER 770 First Avenue, Suite 400, San Diego, CA 92101 p | 619.831.4600 f | 619.232.1039

occur prior to the placement of the channel liner. Using this methodology, differential settlement between the crossing structure and the channel liner can be limited to under 1 inch. Another drawback of this concept is that it requires greater excavation than Concept 2 which, in turn, can impose greater heave on the siphon during the construction sequence. The magnitude of this heave can be reduced by dividing up the footing excavation and placing segments of the footings prior to excavating the full length of the footing.

Concept 2: Relieving Slab on CIDH Concrete Piles

This concept is supported on CIDH concrete piles that rely on skin friction along the length of the pile. The top portion of these concrete piles are cased in a smooth steel casing to limit the transfer of the forces from the piles to the siphon. The main benefit of this concept is that the crossing settlement can be reduced by increasing the pile length. Also, the overall structure width of Concept 2 is 14 feet less than Concept 1, allowing more room in the right of way for future MWD projects. One disadvantage of this concept is that, because the concrete piles are supported on deeper soil layers, the crossing structure may not necessarily settle with the adjacent surface level structures. This means that if significant subsidence or liquefaction occurs, the crossing structure may settle less than the surrounding structures resulting in it ending higher than the adjacent liner. A transition slab was incorporated into this option to mitigate this potential. Additionally, the installation of these piles has the potential to impose significant vibrations on the existing siphon. Preliminary analysis using of Caltrans' Transportation Construction Vibration Guidance Manual (April 2020) showed that drilling shafts at this distance from the siphon without exceeding the sustained peak particle velocity limit of 0.5 in/sec set by MWD is feasible. It should be noted though, there is some uncertainty in this analysis given the variability of soils and equipment.

Proposed Crossing Design

Of the concepts considered, the relieving slab on shallow foundations (Concept 1) was chosen as the proposed crossing type. This crossing geometry was chosen because its main limitations, including large crossing settlements and heave during excavation, can be mitigated to acceptable levels through construction staging. The CIDH concrete piles in Concept 2 present greater risk to the siphon during construction. Additionally, the possibility of the crossing rising above the adjacent channel lining due to the surrounding soil subsiding could infringe on the functionality of the channel. Preliminary plans for the proposed crossing are provided in Attachment 4, and preliminary structural calculations supporting this design are provided in Attachment 5.

Design Criteria

The crossing is designed according to AASHTO LRFD Bridge Design Specifications 8th Edition with Caltrans Amendments, dated August 2019 and Errata dated June 2024 as modified by the project specific Design Criteria Memo dated 01-12-2024 (provided in Attachment 2). In addition to the H-20 design vehicle discussed in the Design Criteria Memo, the anticipated service vehicles used by Riverside County Flood Control, a Volvo EC300E Excavator (36.5 Ton) and a Caterpillar D6 Bulldozer (24.25 Ton), are also considered. These two additional vehicles are treated as typical design vehicles, and their demand is

© 2024 Kleinfelder

included in the live load envelopes for Strength IA and Service IA load combinations. The geometries for these vehicles are presented in Attachment 5.

Settlement Analysis

A preliminary global settlement analysis using PLAXIS 3D was conducted for both concepts and included the adjacent channel berms. This settlement analysis calculated the displacement imposed on the existing siphon due to the crossing structure and berm construction sequence along with the subsequent water and live loading on the crossing and the surrounding area. This analysis determined the necessity of using lightweight fill (preliminarily assumed 30 pcf maximum unit weight) for the channel berms within the vicinity of the siphon (see Attachment 3 for preliminary limits of lightweight fill). Based on this analysis the proposed crossing would satisfy the MWD limit of 0.25 inches of settlement over 100 feet. This settlement analysis is discussed in the Project Geotechnical Investigation Report.

Construction Restrictions and Methods

Restrictions must be placed on staging and methods of construction to mitigate detrimental effects on the siphon during the construction of the crossing structure. These restrictions will be introduced here. Additionally, a preliminary work plan for the construction of this crossing is presented in Attachment 6.

Excavation for the footings shall be conducted symmetrically on either side of the siphon. The excavation and placement of the footings shall be broken into three stages to prevent excessive heave on the siphon. Additionally, to limit vibrational impacts to the siphon, flowable backfill shall be used for backfilling the footing. Placement of this backfill is to be conducted simultaneously on either side of the siphon and in front and behind the footings. A maximum difference in backfill depth of 1 foot is allowable in both locations. Excavation and backfill restrictions are discussed in greater detail in the Project Geotechnical Investigation Report.

MWD requires any excavation within 2 feet of the siphon to be performed with hand equipment. The footings are located such that the 1.5H:1V excavation slope does not infringe in this 2-foot buffer zone. The final cover over directly over the siphon is less than 2 feet and will require infringing on this buffer zone. As discussed in the preliminary work plan (Attachment 5) it is proposed that a vacuum truck be used to safely remove the soil in this region.

The formwork for the stem of the footing shall be supported without bracing against the soil covering the siphon. This can be achieved by bracing against heel of the footing and across to the stem formwork on the opposite side of the siphon. The base of the footing may be poured neat against the sides of the excavation.

SUBJECT: Shea Properties – Line E

Design Criteria Memo

PROJECT DESCRIPTION

This design criteria memo pertains to the proposed crossing structure to span the existing Casa Loma Barrel No. 1 Siphon. The crossing is located just west of the city of San Jacinto in Riverside County, California where the proposed San Jacinto Valley Master Drainage Plan (MDP) Line E storm water channel crosses the existing siphon. The purpose of the crossing structure is to prevent additional loading on the existing siphon due to channel loads including potential maintenance vehicles and water loads. The crossing structure will be placed where soil cover over the existing siphon is reduced to under 4 feet or where warranted by the results of settlement analysis.

DESIGN METHODOLOGY

The crossing will be designed according to AASHTO LRFD Bridge Design Specifications 8th Edition with Caltrans Amendments, dated August 2019 and Errata, dated October 2019 (AASHTO LRFD). Project specific requirements and modifications will be listed in the following sections. The Municipal Water District's (MWD) "Improvement and Construction Guidelines" (dated July 2018) is incorporated into this design criteria.

DESIGN LOAD

The crossing structure will be designed to support a single H-20 truck design vehicle with a multiple presence factor of 1.0. The crossing will be designed to resist the weight of water loading; the water height will match the height of the adjacent canal berms for strength loads cases and will match the 100-year flood level for service load cases. Vehicle loading and water loading will not be considered concurrently. Seismic loading will be checked to ensure the crossing structure does not impart additional seismic surcharge on the existing siphon. The applicable load combinations from the tables below will be used for the design of the crossing structures:

© 2024 Kleinfelder

KLEINFELDER 770 First Avenue, Suite 400, San Diego, CA 92101 p | 619.831.4600 f | 619.232.1039

CROSSING LOAD COMBINATIONS

Load Combination	DC, DD, DW, EH, EV, ES, EL, PS, CR & SH *	LL, IM, CE, BR, PL & LS	WA	TU	EQ
Strength IA	Υ_p	1.75	0	0.5/1.2	0
Strength IB	Υ_p	0	1	0.5/1.2	0
Service IA	1	1	0	1.0/1.2	0
Service IB	1	0	1	1.0/1.2	0
Extreme I	1	0	0	0	1

*Load factors for permanent loads are based on AASTHTO LRFD Table 3.4.1-2

GEOMETRIC LIMITS

The crossing structure will be designed to provide a minimum of 6 inches of undisturbed soil over the top of the Casa Loma Barrel No. 1 Siphon. Additionally, the crossing structure will be designed to allow for a compressible blanket, consisting of 6 inches of expanded polystyrene foam, to be placed between the bottom of the structure and top of the undisturbed soil. This compressible blanket will extend a minimum 1 foot past the edge of the existing siphon. If footings are used for the crossing structure, the edge of the footing will be offset a minimum of 5 feet from the outside of the existing siphon and placed so that a line running at a 45-degree angle from the toe of footing does not intersect the outside circumference of the existing siphon. If driven pile foundations are used to support the crossing structure no portion of the pile will infringe on a region within 20 feet of the center of the existing siphon. If drilled micropile or cast-in-place pile foundations are used, no portion of the pile will be placed within 5 feet of the outside of the existing siphon. If pile foundations are used, the piles will be detailed to prevent down drag forces from being developed above the centerline of the existing siphon.

DISPLACEMENT LIMITS

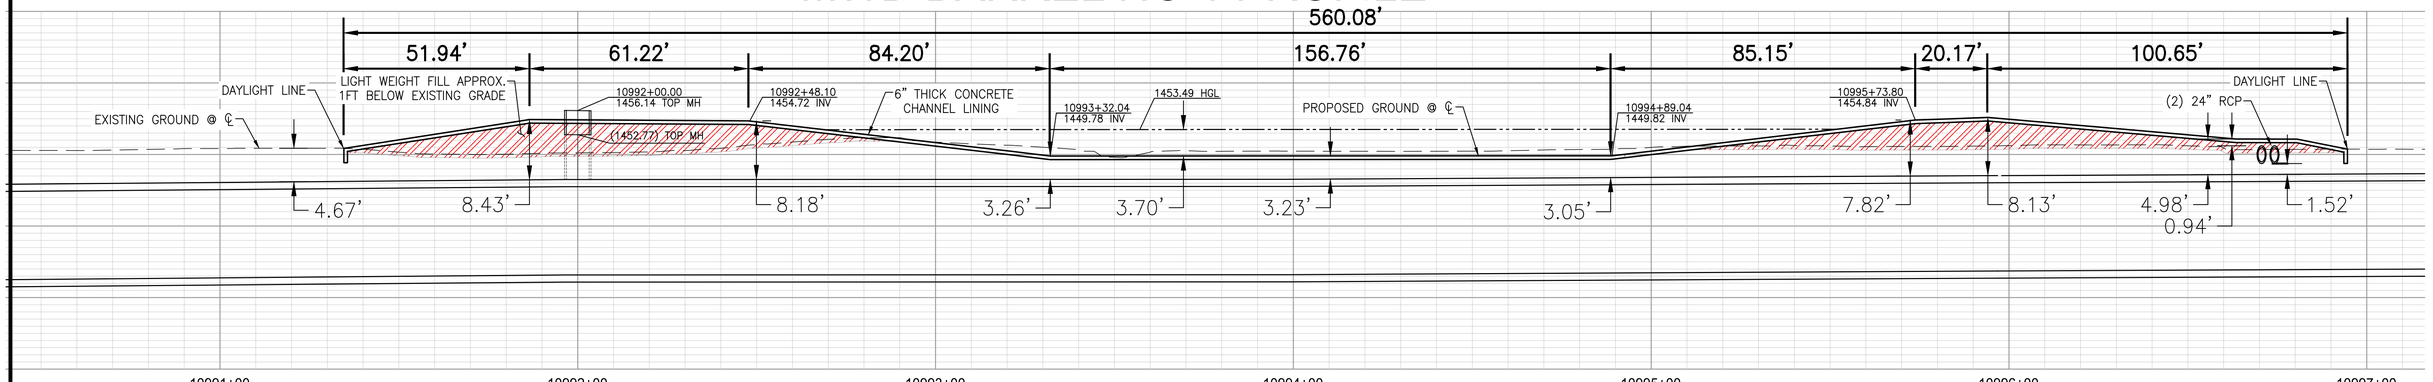
The maximum allowable differential settlement along the length of the existing siphon will not exceed ¼ inch over 100 feet. Differential settlement between the crossing structure and the adjacent channel liner will not exceed 1 inch. The combined crossing long-term structural deformation, short-term structural deformations and soil settlement will not exceed the thickness of the compressible blanket. Service load combinations will be used for the calculation of displacements.

CONCRETE COVER

AASHTO LRFD-CA Table 5.10.1-1 provides minimum concrete cover over reinforcement depending on the components and site conditions. Based on the geotechnical investigation this site is considered a non-marine environment with non-corrosive soil. Therefore, where concrete components are adjacent to soil, a minimum concrete cover of 3 inches will be used. A minimum of 2 inches of cover will be used for any surface exposed to the channel flow. A minimum of 1.5 inches of cover will be used for surfaces adjacent to the polystyrene foam. Where necessary, according to Caltrans Memo to Designer 10-5, these minimum

© 2024 Kleinfelder

covers may be reduced by utilizing epoxy coated rebar (ECR) and/or supplementary cementitious materials (SCM). Cover may be reduced by ½ inch when using post-fabricated ECRs and 1 inch when using pre-fabricated ECRs and/or SCM. By no means will clear cover be reduced below 1 inch.



CRACK CONTROL

AASHTO LRFD Article 5.6.7 provides a check to limit crack width under service level loading. Two design levels are given: Class 1 applies to conditions where a wider crack width is acceptable due to reduced concerns of appearance and corrosion. Class 2 applies where reducing crack width is desirable to improve appearance and corrosion resistance. A Class 2 exposure factor will be used for an surfaces exposed to the channel flow. A Class 1 exposure factor will be used elsewhere.

GENERAL NOTES:

DESIGN SPECIFICATIONS:
AASHTO LRFD BRIDGE DESIGN SPECIFICATIONS, 8TH EDITION 2017, AND THE CALIFORNIA AMENDMENTS, PREFACE DATED APRIL 2019 WITH JUNE 2024 ERRATA

CONSTRUCTION SPECIFICATIONS:

EXISTING CONDITIONS:
BEFORE PROCEEDING WITH ANY WORK, THE CONTRACTOR SHALL REVIEW EXISTING SITE CONDITIONS, VERIFY ALL DIMENSIONS AND VERIFY THE EXACT LOCATION OF EXISTING UTILITIES.

CONCRETE:
SLAB CONCRETE SHALL BE F'C = 5 KSI COMPRESSIVE STRENGTH @ 28 DAYS.
FOOTING CONCRETE SHALL BE F'C =3.6 KSI COMPRESSIVE STRENGTH @ 28 DAYS.

REINFORCING STEEL:
ALL REINFORCING STEEL SHALL BE ASTM A615 GRADE 60

CONSTRUCTION STAGING:
EXCAVATION, FOOTING PLACEMENT AND BACKFILL SHALL BE CONDUCTED CONCURRENTLY AND SYMMETRICALLY ON EITHER SIDE OF THE SIPHON. A MAXIMUM DIFFERENCE OF 1 FOOT IS ALLOWED BETWEEN THE EXCAVATION, CONCRETE AND BACKFILL ON EITHER SIDE OF THE SIPHON. THE PLACEMENT OF THE ADJACENT CONCRETE LINER SHALL OCCUR NO LESS THAN 1 WEEK AFTER THE PLACEMENT OF THE CROSSING SLAB.

BACKFILL:
BACKFILL SHALL CONSIST OF MEDIUM WEIGHT FLOWABLE FILL (UNIT WEIGHT OF 85 PCF ±). BACKFILL ON EITHER SIDE OF THE FOOTING SHALL BE PLACED CONCURRENTLY AND SYMETRICALLY SO THAT THE DIFFERENCE IN FILL DEPTH IS NOT GREATER THAN 1 FOOT.

NOT FOR CONSTRUCTION

Project: Shea Properties
Project #: 20242328
Subject: Project Information

Originator: JRM
Date: 11/07/2024

Project Information

Project Discussion:
The San Jacinto Line E Storm Drain Project involves the design of approximately 3-miles of storm drain channel in the City of San Jacinto, California. Near the end of this proposed storm drain channel it crosses the existing Casa Loma Barrel No. 1 Siphon operated by the Metropolitan Water District (MWD). The construction of this channel requires the removal of some cover over the existing siphon. MWD requires a relieving slab to be constructed over this siphon if the cover is reduced below 4 feet. In order to construct the proposed channel a crossing over this existing siphon must be designed to support both the channel water loading and channel service vehicles.

Location:
San Jacinto, California

Structure Type:
28'-4" Single span 1'-2" deep reinforced concrete slab supported on spread footings.

Slab Design - Excavator and Bulldozer

Included in these calculations are checks for:

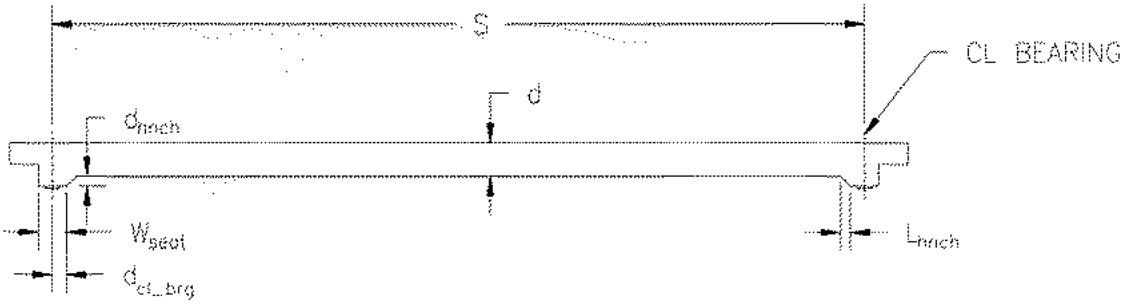
+Flexure
+Minimum Reinforcement
+Crack Control
+Shear
+Longitudinal Reinforcement (Combined Shear-Flexure)

Analysis:

The excavator and bulldozer vehicles that will be used to service this channel have a axle widths and patch loadings inconsistent with the standard AASHTO design vehicles. Because of this the equivalent strip width methodolgy used elsewhere in these calculations is not appropriate. To analyze the force effects of these vehicles an shell model is created in SAP2000. This model uses thick shell elements with a 5" mesh size. The slab is supported by pins at the center of the bearings. Area loads are applied on the slab over the area of the track. The excavator and bulldozer are placed longitudinally and tranversely on the slab as shown on the following sheets.

Section:

$S := 28\ ft + 4\ in = 28.33\ ft$ Span length



$d_{cl_brg} := 6\ in$ Distance to bearing CL

$d := 14\ in$ Slab depth

$d_{hnch} := 4\ in$ Haunch depth

$L_{hnch} := d_{hnch} = 4\ in$ Length haunch

$W_{seat} := 1\ ft$ Seat width

$E := 1\ ft$ Design strip width

$b := E = 1\ ft$ Section width

Material Properties:

Bulldozer - Transverse - Shear

A shear stress concentration was observed near the bearings in all three shear load cases with the maximum magnitude shown in the longitudinal excavator load case.

To determine a clearer demand a model was refined with 1"x1" mesh in the vicinity of the bearing and with the bearing modelled by a number of springs with a realistic total stiffness based on the bearing design. The stress concentration is located within the end diaphragm so demand is taken at the edge of fillet 10" from the CL of bearing.

Spring Stiffness

$\varepsilon_{brg} := 6.95\%$	Bearing compressive strain (see bearing design)
$\sigma_{brg} := 703\ psi$	Bearing compressive stress (see bearing design)

$H := 7.75\ ft$	Wall height
$H_{bw} := t_{slab} + t_{hnch} - t_{end} = 9\ in$	Backwall height
$W_{ft} := 10\ ft$	Length of footing
$t_{liner} := 6\ in$	Liner thickness
$d_{cl_brg} := 0.5\ ft$	Distance to centerline of bearing
$L_{toe} := 0.5\ ft$	Length of footing toe
$t_{bw} := t_{stem} - W_{seat} = 1\ ft$	Backwall thickness
$e_{brg} := 0.5 \cdot W_{ft} - d_{cl_brg} - L_{toe} = 4\ ft$	Bearing load eccentricity from footing center

Demand:

Crossing Slab Dead Loads:

$\gamma_{c_slab} := 150\ pcf$ Crossing slab concrete unit weight

Cross sectional area of crossing slab:

$A_{slab} := S_{slab_clr} \cdot t_{slab} + 2\ \left(0.5 \cdot t_{hnch}{}^2 + t_{end} \cdot t_{bw} + W_{seat} \cdot \left(t_{hnch} + t_{slab}\right)\right) = 36.496\ ft^2$

$P_{SS_DL} := \gamma_{c_slab} \cdot \left(0.5 \cdot A_{slab}\right) = 2.737\ klf$ Tributary slab weight

$M_{SS_DL} := P_{SS_DL} \cdot e_{brg} = 10.949\ \frac{kip \cdot ft}{ft}$ Moment about center of footing

Crossing Slab Water Loads:

$\gamma_w := 62.4\ pcf$ Water unit weight

$h_{w_ser} := 3.7\ ft$ Water depth service loading

$p_{WA_ser} := \gamma_w \cdot h_{w_ser} = 0.231\ ksf$ Pressure due to service water level

Tributary slab water loading:

$L_{slab_trib} := 0.5\ S_{slab_clr} + W_{seat} + t_{bw} = 15.665\ ft$

$P_{SS_WA_ser} := p_{WA_ser} \cdot L_{slab_trib} = 3.617\ klf$

Moments about center of footing

$M_{SS_WA_ser} := P_{SS_WA_ser} \cdot e_{brg} = 14.467\ \frac{kip \cdot ft}{ft}$

Crossing Slab Live Loads:

See calculations at the end of section for the calculation of the distributed live load

$P_{SS_LL} := 3.53\ klf$ — Live load distributed load

$M_{SS_LL} := P_{SS_LL} \cdot e_{brg} = 14.12\ \frac{kip \cdot ft}{ft}$ — Live load Moment

Wall Dead Load:

$\gamma_c := 150\ pcf$ — Typical concrete unit weight

$P_{bw} := \gamma_c \cdot (t_{bw}) \cdot (H_{bw}) = 0.113\ klf$ — Backwall load

$e_{bw} := 0.5\ W_{ft} - (W_{seat} + 0.5\ t_{bw} + L_{toe}) = 3\ ft$ — Backwall eccentricity

$P_{stem} := \gamma_c \cdot (t_{stem})\ (H - (t_{slab} + t_{hnch}) - t_{ft}) = 1.275\ klf$ — Stem load

$e_{stem} := 0.5\ W_{ft} - (0.5\ t_{stem} + L_{toe}) = 3.5\ ft$ — Stem eccentricity

$P_{ft} := \gamma_c \cdot (t_{ft})\ (W_{ft}) = 3\ klf$ — Footing load

$e_{ft} := 0.5\ W_{ft} - 0.5\ W_{ft} = 0\ ft$ — Footing eccentricity

$P_{DC} := P_{bw} + P_{stem} + P_{ft} = 4.388\ klf$ — Dead load

$M_{DC} := P_{bw} \cdot e_{bw} + P_{stem} \cdot e_{stem} + P_{ft} \cdot e_{ft} = 4.8\ \frac{kip \cdot ft}{ft}$ — Dead moment

$e_{DC} := \frac{M_{DC}}{P_{DC}} = 1.094\ ft$ — Dead load eccentricity

Soil Loading:

$\gamma_s := 85\ pcf$ Unit weight of soil

$k_a := 0.33$ Active coefficient of soil

$L_{heel} := W_{ft} - t_{stem} - L_{toe} = 7.5\ ft$ Length of heel

$p_{EV} := \left(H - t_{liner} - t_{ft}\right) \cdot \gamma_s = 0.446\ ksf$ Vertical soil pressure on footing

$P_{EV_heel} := L_{heel} \cdot p_{EV} = 3.347\ klf$ Vertical soil load on heel

$e_{EV_heel} := 0.5\ W_{ft} - \left(L_{toe} + t_{stem} + 0.5\ L_{heel}\right) = -1.25\ ft$ Eccentricity of vert heel soil load

$P_{EV_toe} := L_{toe} \cdot p_{EV} = 0.223\ klf$

$e_{EV_toe} := 0.5\ W_{ft} - \left(0.5\ L_{toe}\right) = 4.75\ ft$

$M_{EV} := P_{EV_heel} \cdot e_{EV_heel} + P_{EV_toe} \cdot e_{EV_toe} = -3.124\ \frac{kip \cdot ft}{ft}$ Moment of Vert soil load on wall

$P_{EV} := P_{EV_heel} + P_{EV_toe} = 3.57\ klf$ Vertical soil load

$e_{EV} := \frac{M_{EV}}{P_{EV}} = -0.875\ ft$ Eccentricity of vertical soil load on heel

$p_{EH} := \left(H - t_{liner}\right) \cdot k_a \cdot \gamma_s = 0.203\ ksf$ Maximum hrz soil pressure

$P_{EH} := 0.5 \cdot \left(H - t_{liner}\right) \cdot p_{EH} = 0.737\ klf$ Horizontal soil load on wall

$e_{EH} := 0.333\ \left(H - t_{liner}\right) = 2.414\ ft$ Eccentricity of hrz soil load

$M_{EH} := P_{EH} \cdot e_{EH} = 1.78\ \frac{kip \cdot ft}{ft}$ Moment of hrz soil load on wall

Liner Surcharge:

$p_{LIN_V} := \gamma_c \cdot t_{liner} = 0.075\ ksf$ Liner vertical surcharge pressure

$P_{LIN_V} := p_{LIN_V} \cdot L_{heel} = 0.563\ klf$ Liner vertical surcharge load

$e_{LIN_V} := 0.5\ W_{ft} - \left(L_{toe} + t_{stem} + 0.5\ L_{heel}\right) = -1.25\ ft$ Liner vertical surcharge eccentricity

$M_{LIN_V} := P_{LIN_V} \cdot e_{LIN_V} = -0.703\ \frac{kip \cdot ft}{ft}$ Moment of liner vertical surcharge

$p_{LIN_H} := \gamma_c \cdot t_{liner} \cdot k_a = 0.025\ ksf$ Liner hrz. surcharge pressure

$P_{LIN_H} := p_{LIN_H} \cdot \left(H - t_{liner}\right) = 0.179\ klf$ Liner horizontal surcharge load

$e_{LIN_H} := 0.5\ \left(H - t_{liner}\right) = 3.625\ ft$ Liner hrz. surcharge eccentricity

$M_{LIN_H} := P_{LIN_H} \cdot e_{LIN_H} = 0.65\ \frac{kip \cdot ft}{ft}$ Moment of liner hrz. surcharge

Water Surcharge:

$p_{WA_V_ser} := \gamma_w \cdot h_{w_ser} = 0.231$ **ksf** — Pressure from service water level

$P_{WA_V_ser} := L_{heel} \cdot p_{WA_V_ser} = 1.732$ **klf** — Load due to service water level

$e_{WA_V} := 0.5\ W_{ft} - \left(L_{toe} + t_{stem} + 0.5\ L_{heel}\right) = -1.25$ **ft** — Water load eccentricity

$M_{WA_V_ser} := P_{WA_V_ser} \cdot e_{WA_V} = -2.165\ \frac{\textbf{kip} \cdot \textbf{ft}}{\textbf{ft}}$ — Moment due to service water load

$p_{WA_H_ser} := \gamma_w \cdot h_{w_ser} \cdot k_a = 0.076$ **ksf** — Hrz pressure from service water level

$P_{WA_H_ser} := \left(H - t_{liner}\right) \cdot p_{WA_H_ser} = 0.552$ **klf** — Hrz load due to service water level

$e_{WA_H} := 0.5\ \left(H - t_{liner}\right) = 3.625$ **ft** — Hrz water load eccentricity

$M_{WA_H_ser} := P_{WA_H_ser} \cdot e_{WA_H} = 2.002\ \frac{\textbf{kip} \cdot \textbf{ft}}{\textbf{ft}}$ — Moment due to service hrz water load

Transverse Bearing Load:

$\mu := 0.2$ — Coefficient of friction between concrete and neoprene

$P_{SS_DL} = 2.737$ **klf**

$P_{brg_H} := \mu \cdot P_{SS_DL} = 0.547$ **klf**

$e_{brg_H} := H - t_{slab} - t_{hnch} = 6.25$ **ft**

$M_{brg_H} := P_{brg_H} \cdot e_{brg_H} = 3.422\ \frac{\textbf{kip} \cdot \textbf{ft}}{\textbf{ft}}$

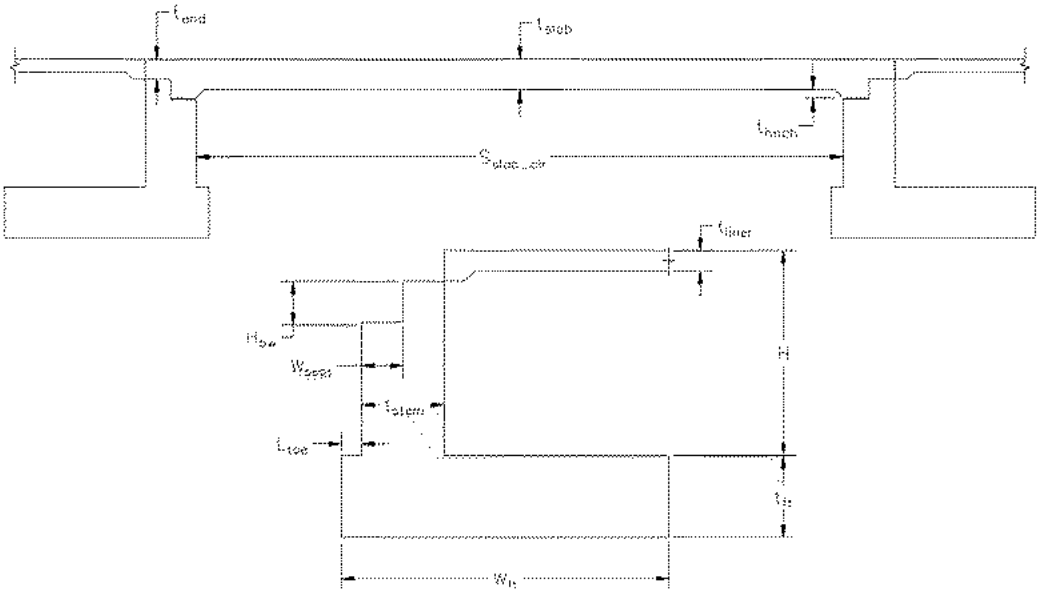
Live Load Bearing Distribution - Transverse Distribution

Transverse H20 Distribution Sketch

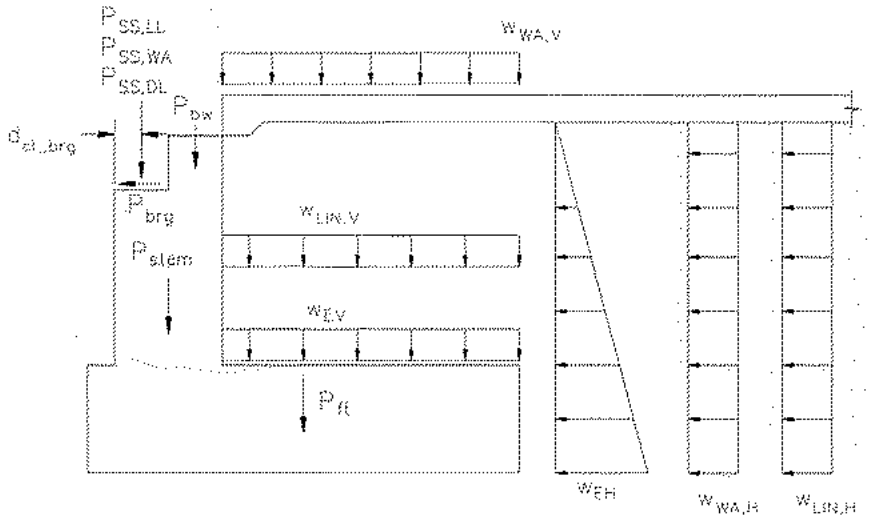
Transverse Excavator/Bulldozer Distribution Sketch



E_{H20_T}	8.58	ft	H20 Transverse distribution length
$w_{LL_H20_T}$	3.53	kip/ft	V_{H20_T}/E_{H20_T}
E_{Ex_T}	20.92	ft	Excavator Transverse distribution Length
$w_{LL_Ex_T}$	3.15	kip/ft	V_{EX_T}/E_{EX_T}
E_{Bd_T}	17.48	ft	Bulldozer Transverse distribution Length
$w_{LL_Bd_T}$	2.62	kip/ft	V_{BD_T}/E_{BD_T}
w_{LL}	**3.53**	kip/ft	Maximum live load distributed load

Wall Global Stability Check

Maximum Footing Height



Crossing Slab Geometry:

$S_{slab_clr} := 27.33\ ft$	Clear slab span
$t_{slab} := 14\ in$	Minimum slab depth
$t_{hnch} := 4\ in$	Depth of haunch
$t_{end} := 9\ in$	Depth slab extension

Foundation Wall Geometry:

$W_{seat} := 12\ in$	Seat width
$t_{ft} := 24\ in$	Footing thickness
$t_{stem} := 24\ in$	Stem thickness
$H := 9.25\ ft$	Wall height
$H_{bw} := t_{slab} + t_{hnch} - t_{end} = 9\ in$	Backwall height
$W_{ft} := 10\ ft$	Length of footing
$t_{liner} := 6\ in$	Liner thickness
$d_{cl_brg} := 0.5\ ft$	Distance to centerline of bearing
$L_{toe} := 0.5\ ft$	Length of footing toe
$t_{bw} := t_{stem} - W_{seat} = 1\ ft$	Backwall thickness
$e_{brg} := 0.5 \cdot W_{ft} - d_{cl_brg} - L_{toe} = 4\ ft$	Bearing load eccentricity from footing center

Demand:

Crossing Slab Dead Loads:

$\gamma_{c_slab} := 150\ pcf$ Crossing slab concrete unit weight

Cross sectional area of crossing slab:

$A_{slab} := S_{slab_clr} \cdot t_{slab} + 2\ \left(0.5 \cdot t_{hnch}{}^2 + t_{end} \cdot t_{bw} + W_{seat} \cdot \left(t_{hnch} + t_{slab}\right)\right) = 36.496\ ft^2$

$P_{SS_DL} := \gamma_{c_slab} \cdot \left(0.5 \cdot A_{slab}\right) = 2.737\ klf$ Tributary slab weight

$M_{SS_DL} := P_{SS_DL} \cdot e_{brg} = 10.949\ \frac{kip \cdot ft}{ft}$ Moment about center of footing

Crossing Slab Water Loads:

$\gamma_w := 62.4\ pcf$ Water unit weight

$h_{w_ser} := 2.2\ ft$ Water depth service loading

$p_{WA_ser} := \gamma_w \cdot h_{w_ser} = 0.137\ ksf$ Pressure due to service water level

Tributary slab water loading:

$L_{slab_trib} := 0.5\ S_{slab_clr} + W_{seat} + t_{bw} = 15.665\ ft$

$P_{SS_WA_ser} := p_{WA_ser} \cdot L_{slab_trib} = 2.15\ klf$

Moments about center of footing

$M_{SS_WA_ser} := P_{SS_WA_ser} \cdot e_{brg} = 8.602\ \frac{kip \cdot ft}{ft}$

Crossing Slab Live Loads:

See calculations at the end of section for the calculation of the distributed live load

$P_{SS_LL} := 3.03\ klf$ — Live load distributed load

$M_{SS_LL} := P_{SS_LL} \cdot e_{brg} = 12.12\ \frac{kip \cdot ft}{ft}$ — Live load Moment

Wall Dead Load:

$\gamma_c := 150\ pcf$ — Typical concrete unit weight

$P_{bw} := \gamma_c \cdot (t_{bw}) \cdot (H_{bw}) = 0.113\ klf$ — Backwall load

$e_{bw} := 0.5\ W_{ft} - (W_{seat} + 0.5\ t_{bw} + L_{toe}) = 3\ ft$ — Backwall eccentricity

$P_{stem} := \gamma_c \cdot (t_{stem})\ (H - (t_{slab} + t_{hnch}) - t_{ft}) = 1.725\ klf$ — Stem load

$e_{stem} := 0.5\ W_{ft} - (0.5\ t_{stem} + L_{toe}) = 3.5\ ft$ — Stem eccentricity

$P_{ft} := \gamma_c \cdot (t_{ft})\ (W_{ft}) = 3\ klf$ — Footing load

$e_{ft} := 0.5\ W_{ft} - 0.5\ W_{ft} = 0\ ft$ — Footing eccentricity

$P_{DC} := P_{bw} + P_{stem} + P_{ft} = 4.838\ klf$ — Dead load

$M_{DC} := P_{bw} \cdot e_{bw} + P_{stem} \cdot e_{stem} + P_{ft} \cdot e_{ft} = 6.375\ \frac{kip \cdot ft}{ft}$ — Dead moment

$e_{DC} := \frac{M_{DC}}{P_{DC}} = 1.318\ ft$ — Dead load eccentricity

Soil Loading:

$\gamma_s := 85\ pcf$ Unit weight of soil

$k_a := 0.33$ Active coefficient of soil

$L_{heel} := W_{ft} - t_{stem} - L_{toe} = 7.5\ ft$ Length of heel

$p_{EV} := \left(H - t_{liner} - t_{ft}\right) \cdot \gamma_s = 0.574\ ksf$ Vertical soil pressure on footing

$P_{EV_heel} := L_{heel} \cdot p_{EV} = 4.303\ klf$ Vertical soil load on heel

$e_{EV_heel} := 0.5\ W_{ft} - \left(L_{toe} + t_{stem} + 0.5\ L_{heel}\right) = -1.25\ ft$ Eccentricity of vert heel soil load

$P_{EV_toe} := L_{toe} \cdot p_{EV} = 0.287\ klf$

$e_{EV_toe} := 0.5\ W_{ft} - \left(0.5\ L_{toe}\right) = 4.75\ ft$

$M_{EV} := P_{EV_heel} \cdot e_{EV_heel} + P_{EV_toe} \cdot e_{EV_toe} = -4.016\ \frac{kip \cdot ft}{ft}$ Moment of Vert soil load on wall

$P_{EV} := P_{EV_heel} + P_{EV_toe} = 4.59\ klf$ Vertical soil load

$e_{EV} := \frac{M_{EV}}{P_{EV}} = -0.875\ ft$ Eccentricity of vertical soil load on heel

$p_{EH} := \left(H - t_{liner}\right) \cdot k_a \cdot \gamma_s = 0.245\ ksf$ Maximum hrz soil pressure

$P_{EH} := 0.5 \cdot \left(H - t_{liner}\right) \cdot p_{EH} = 1.074\ klf$ Horizontal soil load on wall

$e_{EH} := 0.333\ \left(H - t_{liner}\right) = 2.914\ ft$ Eccentricity of hrz soil load

$M_{EH} := P_{EH} \cdot e_{EH} = 3.129\ \frac{kip \cdot ft}{ft}$ Moment of hrz soil load on wall

Liner Surcharge:

$p_{LIN_V} := \gamma_c \cdot t_{liner} = 0.075\ ksf$ Liner vertical surcharge pressure

$P_{LIN_V} := p_{LIN_V} \cdot L_{heel} = 0.563\ klf$ Liner vertical surcharge load

$e_{LIN_V} := 0.5\ W_{ft} - \left(L_{toe} + t_{stem} + 0.5\ L_{heel}\right) = -1.25\ ft$ Liner vertical surcharge eccentricity

$M_{LIN_V} := P_{LIN_V} \cdot e_{LIN_V} = -0.703\ \frac{kip \cdot ft}{ft}$ Moment of liner vertical surcharge

$p_{LIN_H} := \gamma_c \cdot t_{liner} \cdot k_a = 0.025\ ksf$ Liner hrz. surcharge pressure

$P_{LIN_H} := p_{LIN_H} \cdot \left(H - t_{liner}\right) = 0.217\ klf$ Liner horizontal surcharge load

$e_{LIN_H} := 0.5\ \left(H - t_{liner}\right) = 4.375\ ft$ Liner hrz. surcharge eccentricity

$M_{LIN_H} := P_{LIN_H} \cdot e_{LIN_H} = 0.947\ \frac{kip \cdot ft}{ft}$ Moment of liner hrz. surcharge

Water Surcharge:

$p_{WA_V_ser} := \gamma_w \cdot h_{w_ser} = 0.137$ **ksf** — Pressure from service water level

$P_{WA_V_ser} := L_{heel} \cdot p_{WA_V_ser} = 1.03$ **klf** — Load due to service water level

$e_{WA_V} := 0.5\ W_{ft} - \left(L_{toe} + t_{stem} + 0.5\ L_{heel}\right) = -1.25$ **ft** — Water load eccentricity

$M_{WA_V_ser} := P_{WA_V_ser} \cdot e_{WA_V} = -1.287\ \frac{\textbf{kip} \cdot \textbf{ft}}{\textbf{ft}}$ — Moment due to service water load

$p_{WA_H_ser} := \gamma_w \cdot h_{w_ser} \cdot k_a = 0.045$ **ksf** — Hrz pressure from service water level

$P_{WA_H_ser} := \left(H - t_{liner}\right) \cdot p_{WA_H_ser} = 0.396$ **klf** — Hrz load due to service water level

$e_{WA_H} := 0.5\ \left(H - t_{liner}\right) = 4.375$ **ft** — Hrz water load eccentricity

$M_{WA_H_ser} := P_{WA_H_ser} \cdot e_{WA_H} = 1.734\ \frac{\textbf{kip} \cdot \textbf{ft}}{\textbf{ft}}$ — Moment due to service hrz water load

Transverse Bearing Load:

$\mu := 0.2$ — Coefficient of friction between concrete and neoprene

$P_{SS_DL} = 2.737$ **klf**

$P_{brg_H} := \mu \cdot P_{SS_DL} = 0.547$ **klf**

$e_{brg_H} := H - t_{slab} - t_{hnch} = 7.75$ **ft**

$M_{brg_H} := P_{brg_H} \cdot e_{brg_H} = 4.243\ \frac{\textbf{kip} \cdot \textbf{ft}}{\textbf{ft}}$

$DC_{MinR_neg} := \frac{M_{r_min}}{\phi_f \cdot M_n} = 0.566$ <1, OK

Crack Control by Distribution of Reinforcing (AASHTO 2017, 5.6.7):

$s_1 := s = 12\ in$ Spacing of flexure steel

$M_s = 7.63\ kip \cdot ft$
$d_s = 20.655\ in$
$b = 12\ in$
$n = 8$
$d_c := d - d_s = 3.345\ in$
$h := d = 2\ ft$

$$\beta_s := 1 + \frac{d_c}{0.7\ (h - d_c)} = 1.231$$

$\gamma_e := 1$ Assume Exposure Class 1, low visibility

for rectangular sections: $\frac{-b_{cap} \cdot y_{rec}^{\ 2}}{2} + n \cdot A_{s1}\left(d_{s1_n} - y_{rec}\right) + n \cdot A_{s2}\left(d_{s2_n} - y_{rec}\right) = 0$

$a_o := \frac{-b}{2}$
$b_o := -n \cdot A_s$ $A_s = 0.31\ in^2$
$c_o := n \cdot \left(A_s \cdot d_s\right)$

$$y := \frac{-b_o - \sqrt{b_o^{\ 2} - 4 \cdot a_o \cdot c_o}}{2 \cdot a_o} = 2.723\ in$$

$$I_{eff} := \frac{b \cdot y^3}{3} + n \cdot \left(A_s \cdot \left(d_s - y\right)^2\right) = 878\ in^4$$

$$f_{ss} := \operatorname{abs}\left(n \cdot \frac{M_s \cdot \left(d_s - y\right)}{I_{eff}}\right) = 14.957\ ksi$$ Stress in flexure steel at service loading

$$s_{max} := \left(\frac{700\ \gamma_e \cdot ksi}{\beta_s \cdot f_{ss}} - 2\ \frac{d_c}{1\ in}\right) in = 31.319\ in$$

$DC_{CrC} := \frac{s_1}{s_{max}} = 0.383$ <1, OK

Maximum Shear:

Demands at Section:

$V_u = 3.6\ kip$ Vertical shear force on section

+ Shear Calculations:

Transverse Steel:

No steel provided

d_v Calculation:

$f_y = 60\ ksi$ $A_s = 0.31\ in^2$ $d_s = 20.655\ in$

$d_{v1} := 0.72 \cdot (d) = 17.28\ in$

$d_{v2} := 0.9 \cdot (d_s) = 18.59\ in$

$d_v := \max(d_{v1}, d_{v2}) = 18.59\ in$

Vc and Vs calculations (AASHTO 2017, 5.7.3.3):

$f'_c = 3.6\ ksi$
$b_v := b = 12\ in$

$\theta := 45\ deg$

$\beta := 2.0$

$V_s := 0\ kip$ AASHTO 2017, (5.7.3.3-4)

$V_c := 0.0316 \cdot \beta \cdot \sqrt{f'_c} \cdot ksi^{0.5} \cdot b_v \cdot d_v = 27\ kip$ AASHTO 2017, (5.7.3.3-3)

Shear Capacity Calculation (AASHTO 2017, 5.7.3.3):

$\phi V_{n1} := \phi_v \cdot 0.25 \cdot f'_c \cdot b_v \cdot d_v = 181\ kip$

$\phi V_{n2} := \phi_v \cdot (V_s + V_c) = 24\ kip$

$\phi V_n := min(\phi V_{n1}, \phi V_{n2}) = 24.1\ kip$

$DCR := \frac{\text{abs}(V_u)}{\phi V_n} = 0.15$ <1, OK

+Longitudinal Reinforcement Calculation:

Longitudinal Reinforcement (AASHTO 2017, 5.7.3.5):

Flexural Component:

$M_u = 12.12\ \textit{kip} \cdot \textit{ft}$ $d_v = 18.59\ \textit{in}$ $\phi_f = 0.9$

$$D_M := \frac{\text{abs}\left(M_u\right)}{\phi_f \cdot d_v} = 9\ \textit{kip}$$

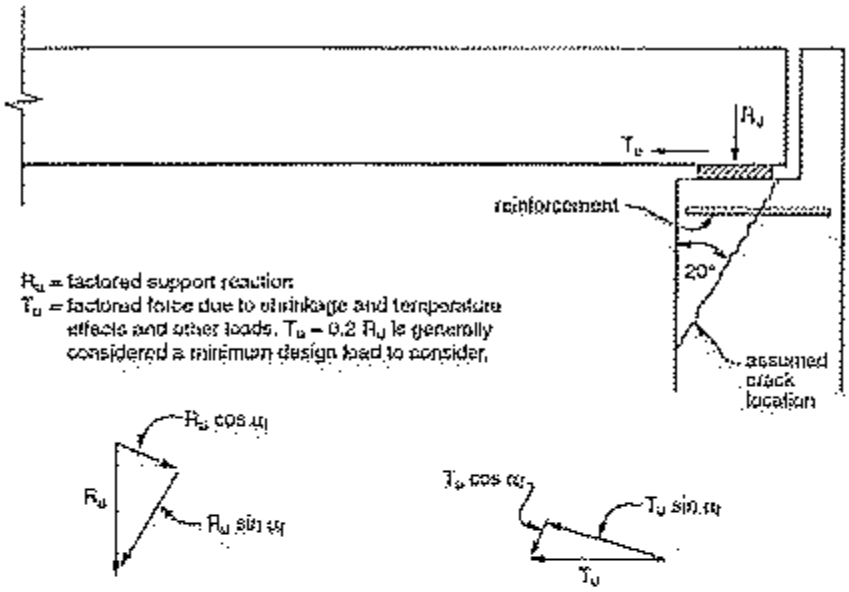
Shear/Torsion Component:

$V_u = 3.6\ \textit{kip}$ $V_s = 0\ \textit{kip}$ $V_p := 0\ \textit{kip}$

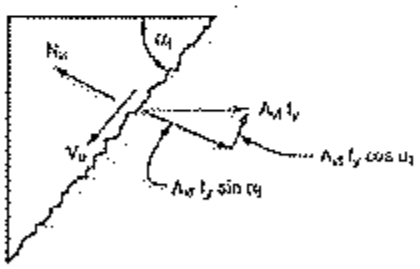
$$V_s := min\left(\frac{\text{abs}\left(V_u\right)}{\phi_v}, V_s\right) = 0\ \textit{kip}$$

$$D_V := \cot\left(\theta\right) \cdot \left(\left|\frac{V_u}{\phi_v} + V_p\right| - 0.5 \cdot V_s\right) = 4\ \textit{kip}$$

Capacity Check:



$A_s = 0.31\ \textit{in}^2$ $f_y = 60\ \textit{ksi}$



$$C := A_s \cdot f_y = 19\ \textit{kip}$$

$$\frac{D_M + D_V}{C} = 0.68$$ <1, OK

Stem Longitudinal Top Reinforcement (BDP 1994, 2-143)

Check the longitudinal reinforcement underneath the bearings.

Applied Forces

$V_u = R_u \sin\alpha_f + T_u \cos\alpha_f$

$N_u = T_u \sin\alpha_f - R_u \cos\alpha_f$

Resisting Forces

$V_n = A_{vf} f_y (\mu \sin\alpha_f + \cos\alpha_f)$ If N_u = tensile force

$V_n = A_{vf} f_y (\mu \sin\alpha_f + \cos\alpha_f) + \mu N_u$ If N_u = compressive force

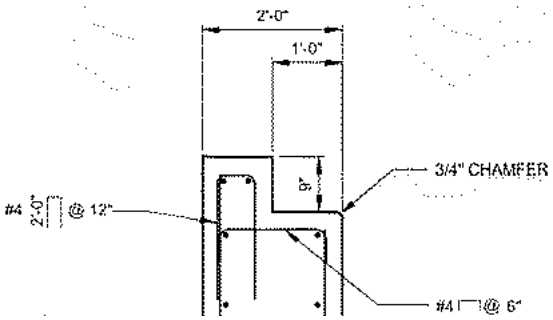
$N_n = A_{vf} f_y \sin\alpha_f$ = nominal tensile strength

Total required steel, $A_s = A_{vf} + A_h$

Distribute steel uniformly along potential crack plane.

$R_u := 67.25\ \textit{kip}$

$R_{perm_fact} := 13.2\ \textit{kip}$



$T_u := 0.2\ (R_{perm_fact}) = 2.64\ \textit{kip}$

$\alpha_f := 70\ \textit{deg}$

$V_u := R_u \cdot \sin(\alpha_f) + T_u \cdot \cos(\alpha_f) = 64.097\ \textit{kip}$ Shear load along failure plane

$N_u := T_u \cdot \sin(\alpha_f) - R_u \cdot \cos(\alpha_f) = -20.52\ \textit{kip}$ Load perpendicular to failure plane (Negative = Compression)

There are #4 @ 6" along the seat, assume a minimum of three fall within failure plane under the 10" long bearing pad

$A_s := 3 \cdot A_{bar}(4) = 0.6\ in^2$

$f_y := 60\ ksi$

$\mu := 1.4$ AASHTO 2017, 5.7.4.4. Monolithically placed concrete

$\phi_v := 0.9$

$l_{d_avail} := 6\ in$

$l_{dh} := 0.67\ ft$

$A_{s_eff} := A_s \cdot \frac{l_{d_avail}}{l_{dh}} = 0.448\ in^2$

$$A_v := \frac{\frac{V_u}{\phi_v} - \max(-\mu \cdot N_u, 0)}{f_y \cdot (\mu \cdot \sin(\alpha_f) + \cos(\alpha_f))} = 0.427\ in^2$$

$$A_n := \max\left(\frac{N_u}{\phi_v\ f_y \cdot \sin(\alpha_f)}, 0\ in^2\right) = 0\ in^2$$

$A_{s_req} := A_v + A_n = 0.43\ in^2$

$\frac{A_{s_req}}{A_{s_eff}} = 0.95$ <1 OK

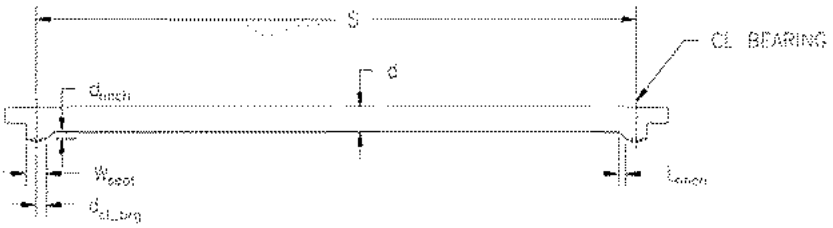
7.3 Slab Seismic Design

Slab Seismic Design



According Caltrans SDC 2.0 section Article 7.2.2 where peak ground accelerations greater than or equal to 0.6g the superstructure shall be design for vertical ground excitation. According to this article these superstructures shall be designed for a uniform load equal to 25% of the superstructes dead load upward or downward. By inspection the strength load case will control for the downward verticle load. This section checks the top mat of reinforcing to resist this upward seismic force.

Section:

$S := 28\ ft + 4\ in = 28.33\ ft$ Span length

$d := 14\ in$ Slab depth

$b := 1\ ft$ Equivalent strip width

Material Properties:

$f'_c := 5\ ksi$ Nominal Concrete strength

$\beta_1 := min\left(0.85, 0.85 - 0.05\left(\frac{f'_c}{ksi} - 4\right)\right) = 0.8$ AASHTO 2017, 5.6.2.2

$\gamma_c := \max\left(145\ pcf + 0.005\ kip \cdot ft^{-3}, 150\ pcf\right) = 150\ pcf$ Concrete modulus of elasticity

$E_s := 29000\ ksi$ Steel modulus of elasticity

Vertical Earthquake Load:

$a_v := 0.25$ Vertical excition coefficent

$w_{EQ_v} := a_v \cdot d \cdot b \cdot \gamma_c = 0.044\ klf$ Load due to vertical siesmic load

$M_{EQ_v} := \frac{w_{EQ_v} \cdot S^2}{8} = 4.39\ kip \cdot ft$ Moment due to vertical siesmic load

Resistance Factors:

$\phi_f := 1$ SDC 2.0, 3.6

+Flexural Calculations:

Longitudinal Reinforcement:

#5s @ 12":

$b_{sz} := 5$ — Bar size

$s := 12\ in$ — Bar spacing

$A_s := b \cdot \frac{A_{bar}(b_{sz})}{s} = 0.31\ in^2$ — Area of longitudinal reinforcement

$f_y := 60\ ksi$ — Nominal yield stress of longitudinal reinforcement

$d_{c1} := 3\ in$ — Cover on longitudinal reinforcement

$d_s := d - (d_{c1} + 0.5\ d_{ba}(b_{sz})) = 10.655\ in$ — Depth to CG of reinforcement layers.

Concrete Compression Block (AASHTO 2017, 5.6.3.1.1):

$c := \frac{A_s \cdot f_y}{0.85 \cdot f'_c \cdot \beta_1 \cdot b} = 0.46\ in$ — AASHTO 2012, 5.7.3.1.1-4

$\varepsilon_t := (d_s - c)\ \frac{0.003}{c} = 0.06712$

$f_{s1} := min(f_y, E_s \cdot \varepsilon_t) = 60\ ksi$

$c := \frac{A_s \cdot f_{s1}}{0.85 \cdot f'_c \cdot \beta_1 \cdot b} = 0.46\ in$

$\varepsilon_t := (d_s - c)\ \frac{0.003}{c} = 0.067$

$f_{s2} := min(f_y, E_s \cdot \varepsilon_t) = 60\ ksi$

$f_s := f_{s2}$

$a := \beta_1 \cdot c = 0.36\ in$ — Depth of equivalent stress block.

Flexural Resistance (AASHTO 2017, 5.6.3.2):

$\phi_f = 1$

$M_{EQ_v} = 4.39 \ \boldsymbol{kip \cdot ft}$

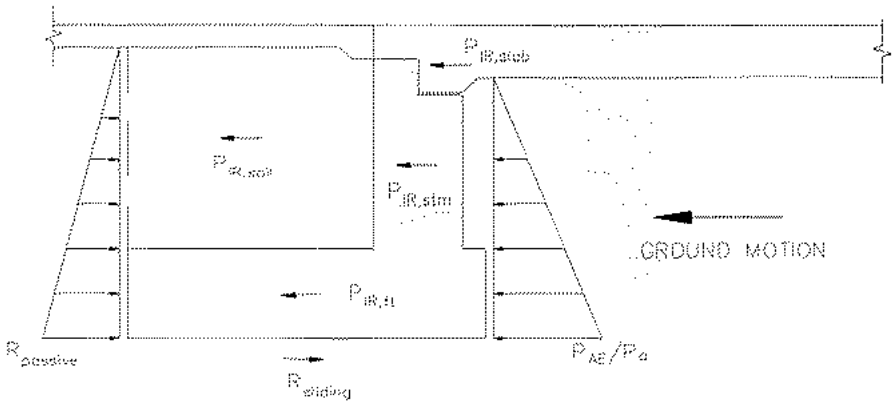
BRIDGE NAME	Crossing Over Casa Loma Barrel 1 Siphon



7.4 Footing Seismic Design

Footing Seismic Design

In a seismic event it is anticipated that the joint between the crossing slab and the footing it is moving towards will close transfering the inertial force from the crossing slab to the footing. This section will check the footings capacity to resist this inertial load

Section:

$S_{slab_clr} := 27.33\ ft$	Clear slab span
$H_{wall} := 9.25\ ft$	Max wall height
$t_{stem} := 2\ ft$	Stem thickness
$t_{ft} := 2\ ft$	Footing thickness
$t_{hnch} := 4\ in$	Haunch thickness
$t_{end} := 9\ in$	Depth slab extension
$\gamma_c := 150\ pcf$	Concrete unit weight
$\gamma_s := 85\ pcf$	Soil unit weight
$L_{toe} := 0.5\ ft$	Length of toe
$W_{ft} := 10\ ft$	Width of footing
$W_{seat} := 1\ ft$	Seat width
$t_{liner} := 6\ in$	Liner thickness
$t_{slab} := 14\ in$	Slab thickness
$b := 1\ ft$	Equivalent strip width
$t_{bw} := 1\ ft$	Backwall thickness
$H_{bw} := 9\ in$	Backwall height
$PGA := 1.062$	Peak ground acceleration

External Stability Checks

The following section will check the external stability of the footing (sliding and bearing checks) to resist the inertial loads of the slab in addition to the the inetials of the footing and the surrounding retained soils.

Vertical Dead Load:

$t_{ft} := 2\ ft$ — Footing thickness

$L_{heel} := W_{ft} - L_{toe} - t_{stem} = 7.5\ ft$ — Heel Length

$d_{cl_brg} := 0.5\ ft$ — Distance to centerline of bearing

Cross sectional area of crossing slab:

$A_{slab} := S_{slab_clr} \cdot t_{slab} + 2\ \left(0.5 \cdot t_{hnch}{}^2 + t_{end} \cdot t_{bw} + W_{seat} \cdot \left(t_{hnch} + t_{slab}\right)\right) = 36.496\ ft^2$

$e_{brg} := 0.5 \cdot W_{ft} - d_{cl_brg} - L_{toe} = 4\ ft$ — Bearing eccentricity

$P_{DL_slab} := \gamma_c \cdot \left(0.5 \cdot A_{slab}\right) \cdot b = 2.737\ kip$ — Slab weight

$\beta := 2.0$

$V_s := 0$ *kip* AASHTO 2017, (5.7.3.3-4)

$V_c := 0.0316 \cdot \beta \cdot \sqrt{f'_c} \cdot \text{ksi}^{0.5} \cdot b_v \cdot d_v = 27$ *kip* AASHTO 2017, (5.7.3.3-3)

Shear Capacity Calculation (AASHTO 2017, 5.7.3.3):

$\phi V_{n1} := \phi_v \cdot 0.25 \cdot f'_c \cdot b_v \cdot d_v = 200$ *kip*

$\phi V_{n2} := \phi_v \cdot (V_s + V_c) = 27$ *kip*

$\phi V_n := min(\phi V_{n1}, \phi V_{n2}) = 26.6$ *kip*

$DCR := \frac{\text{abs}(V_{EQ_ft})}{\phi V_n} = 0.211$ <1, OK

+Longitudinal Reinforcement Calculation:

Longitudinal Reinforcement (AASHTO 2017, 5.7.3.5):

Flexural Component:

$M_{EQ_ft} = -35.475\ kip \cdot ft\ \ d_v = 18.5\ in \qquad \phi_f = 1$

$D_M := \frac{\text{abs}\left(M_{EQ_ft}\right)}{\phi_f \cdot d_v} = 23\ kip$

Shear/Torsion Component:

$V_{EQ_ft} = -5.612\ kip \quad V_s = 0\ kip \qquad V_p := 0\ kip$

$V_s := min\left(\frac{\text{abs}\left(V_{EQ_ft}\right)}{\phi_v}, V_s\right) = 0\ kip$

$D_V := \cot(\theta) \cdot \left(\left|\frac{V_{EQ_ft}}{\phi_v} + V_p\right| - 0.5 \cdot V_s\right) = 6\ kip$

Capacity Check:

$A_s = 0.44\ in^2 \qquad f_y = 60\ ksi$

$C := A_s \cdot f_{ye} = 30\ kip$

$\frac{D_M + D_V}{C} = 0.96$ <1, OK

Backwall Check

In a seismic event it is anticipated that the joint between the crossing slab will close transfering the inertial force from the crossing slab to one of the footings. This force will transfer to the footing through the backwall of the footing. This section will check that the backwall is capable transfering this load

Material Properties:

$f'_c := 3.6\ ksi$ — Nominal Concrete strength

$\gamma_c := 150\ pcf = 150\ pcf$ — Concrete modulus of elasticity

$f_y = (6 \cdot 10^4)\ psi$ — Reinforcing steel stress

Resistance Factors (Caltrans SDC 2.0, 3.6):

$\phi_f = 1$

$\phi_v := 1$

Demand:

$A_{slab} := 36.5\ ft^2$ — Slab cross section area (from footing design)

$P_{slab} := 2 \cdot P_{DL_slab} = 5.474\ kip$

$PGA = 1.062$ — Peak ground acceleration

$P_{IR_slab} := PGA \cdot P_{slab} = 5.814\ kip$ — Load due to vertical siesmic load

$P_{IR_bw} := P_{IR_slab} = 5.814\ kip$

Interface Shear (AASHTO 2017, 5.7.4):

Miminimum Area of Interface Shear Reinforcement (AASHTO 2017, 5.7.4.2)

$t_{bw} = 1\ ft$ $f_y = 60\ ksi$

$b = 1\ ft$

$A_{cv} := t_{bw} \cdot b = 1\ ft^2$

$A_{vf_min} := \frac{0.05 \cdot A_{cv} \cdot ksi}{f_y} = 0.12\ in^2$

use (2) #4s @ 12"

$n := 2$

$s := 12\ in$

$b_{sz} := 4$

$A_{vf} := \frac{n \cdot A_{bar}(b_{sz})}{s} \cdot b = 0.4\ in^2$

Check Interface Shear (AASHTO 2017, 5.7.4.3)

Normal weight concrete placed monolithically:

$c := 0.4\ ksi$	Cohesion factor
$\mu := 1.4$	Friction factor
$K_1 := 0.25$	Fraction of concrete strength available
$K_2 := 1.5\ ksi$	Limiting interface shear resistance
$P_c := 0\ kip$	Compression on interface

$V_{ni_1} := c \cdot A_{cv} + \mu \cdot (A_{vf} \cdot f_y + P_c) = 91.2\ kip$

$V_{ni_2} := K_1 \cdot f'_c \cdot A_{cv} = 129.6\ kip$

$V_{ni_3} := K_2 \cdot A_{cv} = 216\ kip$

$V_{ni} := min(V_{ni_1}, V_{ni_2}, V_{ni_3}) = 91.2\ kip$

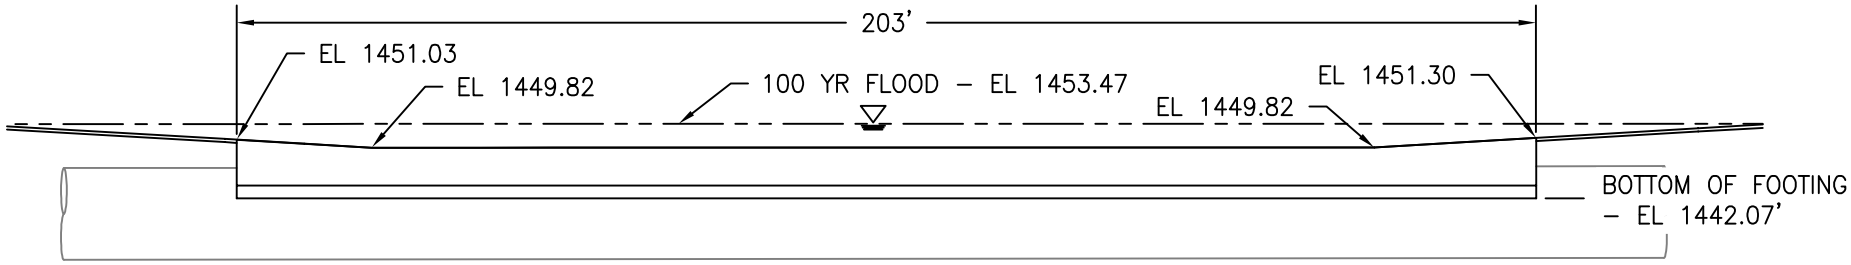
$DCR := \frac{\phi_v \cdot P_{IR_bw}}{V_{ni}} = 0.064$ <1, OK

Mamco Inc dba

alabbasi CONSTRUCTION AND ENGINEERING Lic. No. 883649

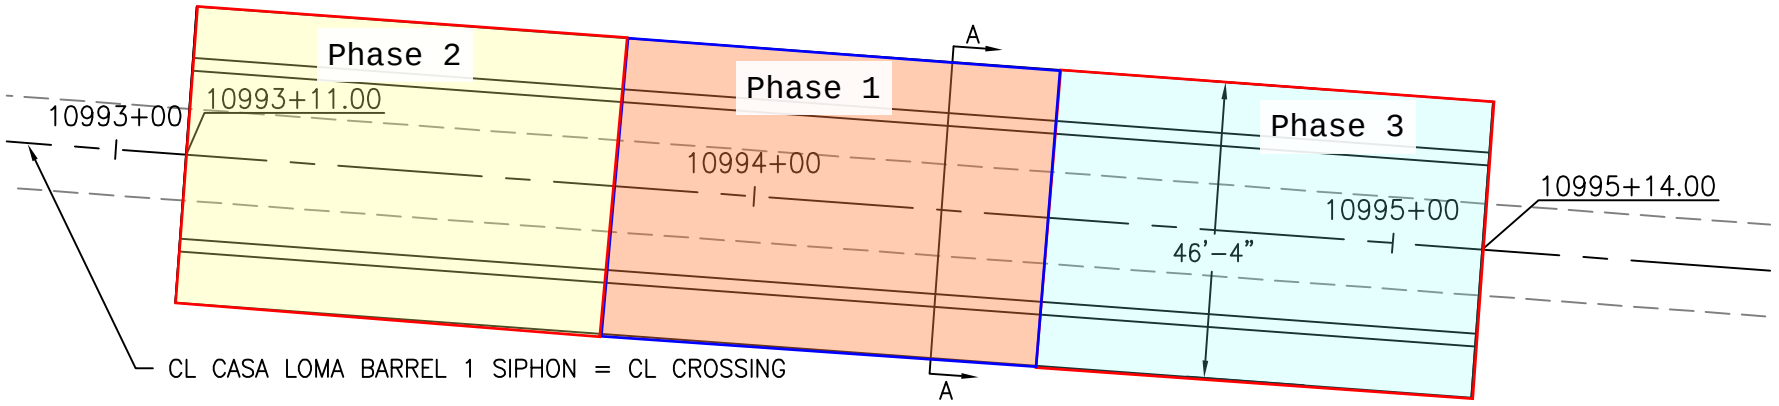
Shea San Jacinto – Casa Loma Barrel Shallow Foundation Work Plan

The Casa Loma Barrel No. 1 will have a shallow foundation constructed per the attached concept. Prior to excavation and construction, the existing line will be located. A vactor truck will slot trench and expose the top of the entire length of the pipeline within the work zone. The work zone will be cleared and grubbed and all vegetation removed and disposed of. The foundation will be constructed in three separate phases per the highlighted plan on the attachment. Each phase will follow the same sequence.



No more than one phase will be excavated to the bottom of the footing at a time. Both sides are to have the same sequence number completed prior to continuing to the next step. Concrete will be placed using a boom pump. No concrete trucks will be permitted to drive within the barrel protection zone.

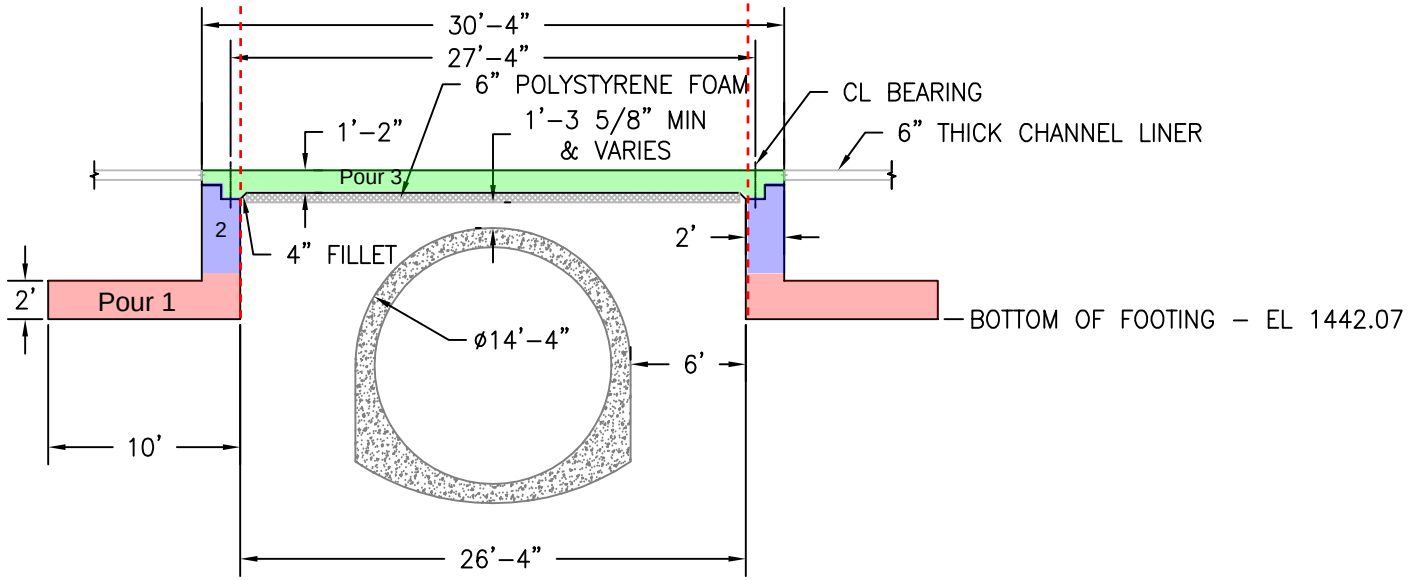
1. The footings will be excavated from North and South concurrently with two Linkbelt 350x excavators. Excavators will be set away from the barrel and each will have a spotter for guidance. The entire footing will not be excavated all at one time on one side. Both sides will be excavated in equal lifts. The excavation will be 10’ wide and 7.75’ deep. Excavated materials will be spoiled behind the excavators and away from the barrel. Spoils will be pushed using a John Deere 644 wheel loader. The temporary excavation will be sloped 1.5:1.
2. The 10’ wide x 2’ high spread footing will be formed and poured first on both sides. The footing will have a 6” starter wall for the next pour.
3. The 5.75’ high footing wall will be formed and poured.



Once sufficient concrete strength has been reached for all footings, the footing will be backfilled with flowable fill to meet the unit weight and strength criteria in the Geotech report.

The top slab over the barrel will be graded using a John Deere 210LE skip loader after which 6” thick polystyrene foam boards will be placed. The top slab will be formed and poured.

ATTACHMENT 6 - PRELIMINARY FOUNDATION WORK PLAN



PROFILE – CONCEPT 1

Protected Zone

PLAN – CONCEPT 1

Protected Zone - No equipment heavier than John Deere 210LE Skip Loader to be used.

150-150	**Add City - Inflow Into Lyon Basin**	**1244**	1205	498	**N/A**
150-150	**Lyon Basin Routing**	71	74	**76**	**N/A**
150-170	**Line-G Flow**	71	74	**76**	**N/A**
170-175	**Line G Flow**	71	74	**76**	**N/A**
175-175	**Store Hydrograph as Stream 2**				
160-160	**Add G-South**	**220**	204	73	**N/A**
160-175	**Storm Drain Routing**	**216**	197	73	
175-175	**Add G-Downstream**	**224**	223	119	**N/A**
175-175	**Add Stream 2**	**225**	223	119	
175-180	**Line G Flow**	219	**220**	119	**N/A**
180-180	**Add E North G**	**378**	365	149	**N/A**
180-185	**Line G Flow**	**377**	360	149	**380**
	MDP LINE E FLOW WEST OF SANDERSON AVE CROSSING				
185-185	**Line- E Flow**	2741	**2968**	1925	***2970***
185-190		2662	**2893**	1923	**N/A**
190-190	**Store Hydrograph as Stream 5**				
136-136	**Add D North B**	**129**	114	37	**N/A**
136-190	**SD Route**	**125**	111	36	
190-190	**Add D North A**	**936**	863	359	**N/A**
	MDP LINE E FLOW PARALLEL TO RECORD RD				
190-190	**Add Stream 5**	3281	**3545**	2172	***3550***
	MDP LINE E FLOW FROM CONFLUENCE BASIN TO NORTH OF RECORD RD				
190-340	**Add Confluence**	3518	**3778**	2256	***3800***
340-340	**Store Hydrograph as Stream 2**				
200-200	**Area W1**	**492**	442	157	**N/A**
200-250	**Line X Flow**	**419**	394	150	**N/A**
200-250	**Add W2**	**1386**	1288	514	**N/A**
250-250	**Store Hydrograph As Stream 3**				
210-210	**Area D1 - Inflow Into Line D Basin**	**1680**	1539	622	**N/A**
210-210	**Line D Basin Routing**	615	**620**	431	**620**
210-215	**Line D Flow**	615	**620**	431	**N/A**
215-215	**Store Hydrograph as Stream 5**				
214-214	**School Subarea**	**512**	476	149	**N/A**
214-215	**Store Hydrograph as Stream 4**				
214-215	**Add Stream 4 at Constant Rate of 10 cfs to Simulate Pump in Taquitz High School Basin**				
215-215	**Add Stream 5**	625	**630**	441	**N/A**
215-220	**Line D Flow**	625	**629**	441	**N/A**
220-220	**Add D2**	735	**775**	511	**775**
220-230	**Line D Flow**	722	**766**	511	**N/A**
230-230	**Add D3**	902	**924**	566	**925**
230-250	**Add Stream 3**	**2288**	2194	999	**N/A**
240-250	**Add D4 - Total Flow into Casa Loma Basin**	**2551**	2459	1093	**N/A**
250-250	**Casa Loma Basin Routing**	395	409	**410**	**410**
250-290	**Line Y-1 Flow**	395	409	**410**	**410**
290-290	**Store Hydrograph as Stream 4**				
260-260	**Add W3**	**228**	210	75	**N/A**
260-270	**Improved Channel (Line Y) Flow**	**198**	183	72	**N/A**
270-270	**Add W4**	**350**	336	131	**N/A**
270-280	**Improved Channel (Line Y) Flow**	**330**	321	127	**N/A**
280-280	**Store Hydrograph as Stream 5**				
280-280	**W5cove Inflow to Cove Basin**	**958**	879	362	**N/A**
280-280	**Cove Basin Routing**	**718**	703	336	**N/A**
280-280	**Add Stream 5**	**1047**	1024	464	
280-280	**Add W6**	**1107**	1074	496	**1110**
280-290	**Line Y Flow**	**1101**	1073	494	**N/A**
290-290	**Add Stream 4**	**1439**	1430	811	**1440**
290-300	**Line Y Flow**	**1430**	1418	809	**N/A**
300-300	**Add W7**	**1513**	1486	887	**1515**
300-310	**Line Y Flow**	**1507**	1478	886	**N/A**
310-310	**Add W8**	1653	**1708**	975	**1710**
310-320	**Line Y Flow**	1649	**1687**	974	**N/A**
320-320	**Add W9**	1798	**1827**	1044	**1830**
320-330	**Line Y Flow**	1794	**1825**	1043	**N/A**
330-330	**Add W10**	1826	**1849**	1073	**1850**
330-340	**Line Y Flow**	1823	**1845**	1072	**N/A**
	MDP LINE E FLOW OVER MWD RW				
340-340	**Add Stream 2**	5083	**5431**	3291	***5440***
340-350	**Line Z Flow**	4972	**5266**	3289	**N/A**
